Many artificial pneumothorax workers are now of the opinion that this form of therapy is most valuable for patients with minimal lesions. In the past, such lesions have been diagnosed so rarely, and when found so many workers believed that pneumothorax was too drastic for them, that very few reports show the results of artificial pneumothorax on minimal lesions. However, with modern methods of diagnosis, including the tuberculin test and the x-ray film, particularly when used as a part of the periodic examination in the physician's office and in special case-finding campaigns, the percentage of cases found presenting minimal progressive pulmonary tuberculosis is definitely increasing. The disease is found before it has produced symptoms, before great destruction of lung tissue has occurred, and before tubercle bacilli are being eliminated. In these cases, physical signs usually are absent. The diagnosis is made largely by the tuberculin test and the roentgen examination. One is not justified in instituting artificial pneumothorax every time a shadow, minimal in extent, is found in the lung. The roentgen examination is not sufficiently refined to determine on first examination with a high degree of accuracy whether the lesion is of long standing and well controlled or is recent and progressive. To collapse a lung containing the former type of lesion is to do definite injustice to the patient and much unnecessary work. Therefore, before instituting collapse therapy one should keep the lesion under observation long enough to determine that it is progressive. Whenever this fact is established, no matter how small the lesion, it is none too early to institute artificial pneumothorax. To wait until the disease has become extensive, cavities have formed and adhesions are binding the lung at least in part to the chest wall is just as ridiculous as to wait until the appendix has ruptured before performing appendectomy.

I now have approximately fifty patients under observation whose artificial pneumothorax was instituted when the disease was minimal. To date, the results in this group are superior to those in other groups under my care who had artificial pneumothorax instituted after the disease had become moderately or far advanced. The results are also superior to those of other groups of minimal cases whom I have observed as they were treated by bed rest alone. I am convinced that, if the lesions are minimal when the treatment is begun, strict bed rest is necessary for only a short time, if at all, and in most cases the period of hospitalization when necessary can safely be limited to a few weeks. Thus, from the standpoint of rendering the sputum negative, of obtaining good results, that is, restoring good working capacity in a high percentage of cases and saving of the patient's time, the earlier in the course of the disease the treatment is begun, the better.

Any physician practicing artificial pneumothorax therapy to a considerable extent will be confronted with lesions in all stages from minimal to far advanced. The answer to the frequently asked question when should artificial pneumothorax be instituted is to attempt it in all unilateral cases at the earliest possible moment

after the disease is known to be progressive, no matter how minimal or how advanced except when the foregoing contraindications are present. When both lungs are involved, that of the more extensive and progressive disease should be collapsed, provided the better lung is or becomes sufficiently clear to carry on the necessary respiratory functions. The physician frequently meets considerable disappointment, since a fair percentage of patients in whom artificial pneumothorax is definitely indicated as determined by the extent of the lesion have extensive or complete obliteration of the pleural cavity through the development of adhesions. For this group, strict bed rest is indicated and should be supplemented by phrenic exeresis, extrapleural thoracoplasty and extrapleural pneumolysis if necessary. Even though the prognosis is not as favorable in far advanced cases, artificial pneumothorax should be attempted when the better lung appears sufficiently free from disease. Good results are obtained in enough such cases to justify giving every patient the advantage of a trial of artificial pneumothorax. Obviously, the less extensive the disease, the better the general condition of the patient; and the fewer the extrapulmonary complications, the better is the patient's risk.

When one sees the mother with extensive pulmonary tuberculosis, first detected by reason of symptoms a few days or a few weeks after delivery, one can be reasonably certain that the disease did not develop suddenly; that in all probability it had been present in a detectable form long before the pregnancy began. Therefore, many disasters can be avoided when all physicians insist on a careful chest examination, including the x-ray film, of every pregnant woman as early in the course of pregnancy as possible. In the Minneapolis General Hospital and Minnesota General Hospital, there is close cooperation between the obstetric and the chest services. Every woman who presents herself for obstetric care is referred to the chest clinic, where the tuberculin test is administered and x-ray films of the chest are made of all positive reactors. Obviously, if the private practitioners of this country, who do the bulk of medical work, will adopt the same procedure, they will be rewarded many times for their effort through finding in the chest of pregnant women tuberculous lesions previously unsuspected. Often these lesions can be successfully treated by artificial pneumothorax and the pregnancy allowed to continue without any harm to the mother. In our experience, delivery is not rendered more difficult after the institution of artificial pneumothorax. The mother's sputum is prevented from becoming positive or, if positive when the lesion is detected, it may be rendered negative. Although it does not seem wise for such mothers to nurse their infants, they may remain in the home as safe associates of their families. The physician who detects and treats such cases renders a service of inestimable value to the patient, the family and the community. He not only often saves the mother's life or prevents a long period of invalidism, but he protects her children, her husband and many members of the community against contamination with tubercle bacilli.

In the past, artificial pneumothorax has been used very extensively among ambulatory patients. However, most of these patients were submitted to a long period of bed rest after artificial pneumothorax had been instituted. They were later allowed to become ambulatory and return to work, while the artificial

pneumothorax treatments were continued. In recent years it has been found that many patients with pulmonary tuberculosis may have artificial pneumothorax instituted without being subjected to strict bed rest, or at most to a few weeks of such rest, while the treatment is being instituted. Reports of the results of such treatment coming from various parts of the world, including a few centers in this country, are very encouraging. Patients on ambulatory treatment from the beginning must be very carefully selected. They will be found among individuals who have minimal or moderately advanced unilateral lesions which are definitely progressive but which have not yet caused serious illness. There should be no significant tuberculous or nontuberculous complications. The sputum may be negative or positive. If it is negative or none is present, one may direct the disease toward healing rather than let it go on progressing. If it is positive, collapse will often render it negative or entirely absent in a short time. The physician often sees patients with advanced disease, mostly unilateral, who refuse hospitalization or do not require it; that is, their general condition is good, they have reasonably good working capacities, but there is always the danger of their bacilli spreading to other parts of the body and to their associates. To collapse the diseased lungs of such patients while they remain ambulatory is a service not only to them but to their communities.

Tuberculosis is frequently seen among elderly persons. While the disease may not cause them serious illness and may not cut short their lives, it may be very dangerous to their associates. In such cases artificial pneumothorax, when possible, protects the community against the spread of their tubercle bacilli while the patients remain ambulatory.

Thus there is a considerable percentage of patients with pulmonary tuberculosis who may now be treated with a short or no period of hospitalization. They avoid the mental complications that so frequently develop from long periods of hospitalization, they are permitted to enjoy their homes, and they continue their earning capacity. We now have under treatment approximately seventy-five such patients who in times past, when we believed it was necessary to hospitalize them, would have cost the taxpayers approximately \$75,000 a year. To date, the results have been as good as those obtained in other cases that were treated both by strict bed rest and by collapse. Moreover, the extension of this work to larger numbers of patients makes available beds in institutions, where patients with disease so advanced that it cannot be treated successfully may be isolated.

Artificial pneumothorax is indicated in children only when the lesions are of the reinfection type. Unfortunately, unless tuberculin tests have been administered periodically it is difficult to differentiate between the lesions of the first infection type in the inflammatory stage and lesions of the reinfection type in the infiltrative stage. However, a period of observation often aids in such differentiation. Lesions of the first infection type usually cause slight or no symptoms. They reach their maximum development in a short time, remain stationary, and then begin to resolve, whereas lesions of the reinfection type usually show a tendency to increase in size sooner or later, cause symptoms and present definite evidence of fibrosis, cavitation and other conditions. There is rarely, if ever, any justification

for inducing artificial pneumothorax in the case of a child who has the first infection type of tuberculosis. This statement applies also to the first infection type of tuberculosis in adults. Among 149 children whom we have observed with the first infection type in the inflammatory stage over a period of one to twelve years at the Lymanhurst School, we have not instituted artificial pneumothorax in a single case. When the lesion is found to be of the reinfection type and is demonstrated to be of a progressive nature, no matter how small it is or how young the child, artificial pneumothorax is recommended. This procedure does not lead to deformity unless complications arise, such as empyema; therefore one need have no hesitancy in administering artificial pneumothorax during the period of childhood.

The question which artificial pneumothorax patients most frequently ask the clinician is When may I discontinue the treatments? Unfortunately, symptoms, physical signs and x-ray films are not safe criteria in answering this question. No one can determine with certainty when the tuberculous lesion is so well under control that it will not reactivate if allowed to reexpand. In the earlier days of this work, the lung was usually allowed to reexpand too soon. The disappearance of symptoms and the marked improvement in the patient's general condition led to a false sense of security on the part of the patient as well as of the physician. Experience soon taught us however that, if permanent results were to be obtained, the lung should be collapsed over a long period. No one can lay down a rule as to just how long the treatment should be continued. This is a problem that must be solved for each individual patient. It must depend on several factors, such as the extent of disease when the treatment is instituted, size of the cavities, presence of tubercle bacilli in the sputum, tuberculous and nontuberculous complications, and the patient's general condition. In minimal cases one hesitates to allow the lung to reexpand in less than two years. In moderately or far advanced cases the lung should be kept collapsed for a period of at least three to five years and in many cases much longer; in fact, when large cavities are present and the involvement is extensive when the treatment is instituted, it is doubtful whether the lung should ever be allowed to reexpand. The red cell sedimentation rate, as recommended by such workers as Cutler, may prove a valuable index on this subject. He is of the opinion that, by observing this rate carefully and periodically throughout the course of treatment, one can determine with a reasonably high degree of accuracy when the lesion is well under control.

A very unfortunate fact about artificial pneumothorax work is that one is not able in all cases to continue the collapse as long as one desires. In a fair percentage of patients, adhesions develop in the pleural cavity and finally obliterate the pneumothorax space. The development of such adhesions may be rapid, so that the space is lost in a short time, or it may be slow, thus permitting one to continue the treatment with a partial collapse over a long period of time. When it is obvious that such adhesions are developing, particularly if the space is being lost fairly fast, oleothorax should be instituted at once. In such cases gomenol (an oil obtained from *Melaleuca viridiflora*) may be used, although many workers are of the opinion that sterilized liquid petrolatum or olive oil has an equally good effect.

Thus, through the replacement of air with oil, further development of the obliterative adhesions is prevented or definitely retarded and the lung may be kept collapsed over the desired period of time. Because of complications that sometimes arise with oleothorax, it is not yet considered a substitute for artificial pneumothorax except in special cases.

Other Pulmonary and Bronchial Conditions.—Artificial pneumothorax has been used to some extent in the treatment of bronchiectasis and pulmonary abscess. Although it has not been found as valuable in these conditions as in pulmonary tuberculosis, it is very much worth while in properly selected cases.

Lobar Pneumonia.—One of the recent developments in artificial pneumothorax work has been its administration to patients suffering from lobar pneumonia. In 1921 Friedman reported the results of artificial pneumothorax in seven cases of pneumonia. Since that time, several workers in other countries have used it and the reports to date, although they cover a limited number of patients, are very encouraging. The more recent observations were reported by Coghlan in January 1932 and by Li in September 1932. Each treated six cases. The treatment resulted in almost immediate relief of symptoms, such as fever and pain. In short, artificial crises appeared soon after the treatment was instituted. In fact, fifty cases have been reported in other countries, with forty-seven recoveries.

In this country, Moorman of Oklahoma City instituted artificial pneumothorax in the treatment of two cases of pneumonia in 1930. Lieberman and Leopold of Philadelphia reported the results of their work on therapeutic pneumothorax in experimental lobar pneumonia in dogs in March 1934. They produced lobar pneumonia in thirty-six dogs, eighteen of which were used as controls and eighteen were treated by artificial pneumothorax. Of the treated dogs, fifteen recovered and three died; of the untreated dogs, five recovered and thirteen died. Two of the treated dogs probably died from another cause; thus, the results of treatment were exceptionally good. Of this work Stengel says:

These results were so confirmative of the clinical experiences reported by several persons . . . that we proceeded to try the treatment in man.

Again he says:

While this method seems to be a step of value in the treatment of pneumonia, I think it should be emphasized and reemphasized that this is not a treatment which in the state of our present knowledge should be regarded as applicable to influenzal pneumonias or diffuse streptococcal pneumonias, nor should it be used, in my opinion, in any case of pneumonia that is recognized at the time as being in any degree bilateral, even with a small lesion on the opposite side.

In May 1934 Blake of New Haven reported his results in the treatment of twenty early cases of pneumococcal lobar pneumonia by artificial pneumothorax on or before the fourth day of disease. Eleven of his patients had a free pleural space, and all recovered promptly by crisis or rapid lysis with no complications except a sterile pleural effusion in one. In the remaining nine cases, preexisting pleural adhesions were present, which prevented adequate collapse. Although none of these patients died, the disease appeared to run its natural course and two developed empyema.

In June 1934 Behrend and Cowper reported the results of treating eleven patients with unilateral lobar

pneumonia by artificial pneumothorax. Nine patients recovered, and two died, but neither of the fatalities could be directly attributed to the pneumothorax.

Stengel says:

The very prompt development of a crisis in patients with marked but early lobar pneumonia and the almost immediate improvement in all subjective symptoms is very striking. Taking all the cases together the mortality of pneumonia under this treatment will probably be distinctly limited but it is to be remembered that certain complicating conditions, such as bilateral involvement, the presence of dense pleural adhesions, etc., interfere with the appropriateness and effectiveness of the treatment and possibly these cases may also be those which contribute to elevating the mortality rate of this disease under any kind of treatment. If the mortality from pneumonia were in no degree lowered by pneumothorax, it might still be said that the prompt improvement and the speedy termination of the disease secured by pneumothorax treatment would still constitute a very decided advance.

SUMMARY

1. Forlanini in Italy collapsed a diseased lung in 1892. Murphy of Chicago in 1898 reported a group of cases treated by artificial pneumothorax.

2. Filtered air to the amount of from 200 to 250 cc. is introduced, under carefully observed manometer readings, into the pleural cavity as an initial treatment. The second treatment is given forty-eight hours later; the third seventy-two hours after the second, and the fourth about five days later. The interval between subsequent treatments depends on the extent of collapse and the rate of absorption of air.

3. The complications are gas embolus, spontaneous or accidental pneumothorax, serous effusion, empyema, mediastinal hernia, febrile reactions, pain and subcutaneous emphysema.

4. Artificial pneumothorax has no deleterious effect on normal lung tissue or the other organs, such as the heart. Diseased tissue collapses more readily than normal tissue, so that selective collapse may result.

5. Artificial pneumothorax may be used as a diagnostic measure.

6. Hemorrhage and minimal progressive to far-advanced unilateral pulmonary tuberculosis are indications for pneumothorax. Even bilateral disease, if one lung is not too extensively involved, responds to pneumothorax treatment. Contraindications are cardiac disease, asthma, severe emphysema and advanced bilateral tuberculosis.

7. In moderately and far-advanced cases, successful pneumothorax shortens the period of bed rest necessary, renders the sputum negative, and closes cavities if the walls are not too thick. In minimal progressive lesions it prevents the sputum from becoming positive or, if positive, renders it negative and controls the disease and frequently obviates hospitalization and strict bed rest.

8. Pregnancy is an indication for rather than against pneumothorax, if the disease is discovered at that time because of the beneficial effect for the patient and the possibility of changing the sputum to negative.

9. Treatment by pneumothorax with the patient remaining ambulatory is possible for selected cases, including elderly persons.

10. Pneumothorax is indicated in children if the lesion is of the reinfection type.

11. Several factors must be kept in mind when discontinuation of pneumothorax is acceded to. Minimal cases should continue at least two years, and moderately

or far-advanced cases from three to five years or even longer.

12. Oil may be substituted for air if adhesions are forming and obliterating the pleural cavity.

13. Pneumothorax is used to some extent in bronchiectasis, pulmonary abscess and lobar pneumonia.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed.

THERAPY OF ECZEMA (DERMATITIS)

This disorder is a noncontagious exudative inflammation of the skin.

THE CAUSE

The cause is twofold in all cases of true eczema: an irritant (exciting cause) and a special irritability (predisposition) of the skin. Without the latter, one has to deal with simple acute dermatitis. Eczema is always a chronic disease, with, however, a tendency to acute exacerbations.

Exciting Causes.—These must always be looked for and eliminated when discovered. Several of these may act simultaneously. They may be:

(a) Chemical: Occupational poisons, as acid, alkalis, turpentine, formaldehyde, toilet articles such as strong soap, dyes (e. g., paraphenylenediamine, which is also used to stain furs), ingestion of medicines.

(b) Mechanical: Friction of opposing surfaces, woolen underwear, scratching (as on account of animal parasites), pressure.

(c) Thermal: Heat or cold.

(d) Actinic: The sun's rays.

(e) Allergens: For methods of discovery see "Allergy."

(f) Micro-Organisms: Though not perhaps a primary cause, these may act as secondary invaders, aggravating the condition and delaying its healing.

In localized involvement there is a strong probability of the existence of a localized exciting cause, just as in generalized involvement a general (predisposing) cause is probably present.

Predisposing Causes.—These may be found in:

(a) The Condition of the Skin: It is desirable to distinguish between the dry, parchment-like skin in which soap as well as roentgen therapy must be avoided and in which bland oils should be used for cleansing and ointments after baths (these patients are better in summer than in winter) and the oily, seborrheic skin, in which roentgen rays are useful to reduce the activity of the sebaceous glands, which may be benefited by reduction in carbohydrate and in which sulphur is likely to be useful.

(b) Digestive Disturbance: Feeding must be at regular intervals, nothing being allowed between meals. The feces should be examined for excess of starch (blue with iodine) or fat. In infants, if the stools are acid, green and loose, sugar restriction is indicated.

(c) Nutritional Disturbance: In the overweight individual, feeding should be reduced quantitatively as well as qualitatively (especially carbohydrate). In the underweight patient the malnutrition must be corrected.

(d) Allergy: Allergy (q. v.), most commonly in infants and to egg, milk, wheat, demands exclusion of the offending food from the dietary.

(e) Systemic Disease: In such conditions as diabetes or nephritis the skin is a great storage area for sugar, salt and water. Reduction of salt and of sugar intake may be of special value in exudative skin disease.

(f) Focal Infection: This may lower resistance, and its removal may be required for cure.

(g) Circulatory Impairment: Eczema of the lower third of the leg may be maintained by varicose veins (q. v.).

(h) Disturbance of the Nervous System: As the skin has the greatest vasomotor nerve supply in the body, disturbance of the nervous system, most especially of emotional nature, may prevent healing or cause exacerbations. The "blush area" is particularly affected in this manner.

LOCAL THERAPY

Local therapy requires recognition of three stages: the acute stage, the subacute stage and the chronic stage.

Acute Stage.—In the acute stage, soothing treatment is required. One should avoid water and hypotonic solutions (which increase swelling), ointments (which interfere with drainage and favor proliferation of micro-organisms in the retained exudate), and irritants of all kinds, such as disinfectants, soaps, chafing, rubbing and most especially scratching (for infants, light elbow splints). To remove crusts, a starch poultice (see impetigo) should be used; for cleansing, olive oil or cold cream, a boric acid solution, or a colloid bath (e. g., three cupfuls of oatmeal gruel in a gauze bag, which is squeezed until the warm water becomes opalescent; a cupful of sodium bicarbonate added to the bath enhances its antipruritic value).

(a) Cooling Lotions: The cooling effect is produced by their evaporation: hence they must not be applied under an occlusive dressing. They should be used either in the form of compresses, if drainage is aimed at, or as drying applications for protection. Compresses are especially valuable to "clear up" infection.

PRESCRIPTION 1.—Menthol-Boric Acid Solution

℞ Menthol	0 015 Gm.
Boric acid	10 00 Gm.
Water	500 00 cc.

Apply on gauze compress.

and cold boric acid solution is probably as good as any, provided it is not permitted to dry. If itching is severe, the addition of a minute amount of menthol (prescription 1) may be permissible. Keeping the compress moist is best done by frequent changing of the top dressings without disturbing the lowest layer, to avoid mechanical irritation. When the acutest stage has passed, solution of aluminum subacetate, diluted 1 to 10 and later 1 to 5, is useful. It may be borne in the acutest stage if diluted with ice cold milk. Whenever such moist applications are used, it is well to protect the healthy skin surrounding the lesion with Zinc Paste.

If a drying effect is desired, Calamine Lotion, dabbed on frequently, is likely to be useful on "weeping" surfaces. If crusts form after a repeated reapplication, these need to be removed by means of sweet oil, which may then be removed by a small quantity of egg yolk gently worked up into an emulsion with a little water (Glaze's method).

If Calamine Lotion is found too drying, Calamine Liniment, which is a cream lotion rather than a liniment (because it is not applied by rubbing), might be useful.

PRESCRIPTION 2.—Calamine Liniment with Phenol

℞ Phenol, liquefied	0 60 cc
Calamine liniment	120 00 cc

Apply freely.

If the itching seems excessive, the addition of a small proportion (0.5 per cent) of phenol (prescription 2) or of menthol or of both, may be admissible. On the whole, however, the less that is used of an irritant antipruritic in acute eczema, the better.

(b) Dusting Powders: Powders that are very fine and clinging such as talcum or zinc stearate, protect inflamed skin against friction, light and moisture and hence are especially important in the acute erythematous or the papular (dry) stage of eczema and between opposing body surfaces to prevent chafing. They should be applied liberally by means of a cotton wad. When the back is affected, body and bed linen should be thickly strewn with it, producing a "powder bed."

Subacute Stage.—In the subacute stage the applications may be mildly stimulating, antiseptic and antipruritic. When one is in doubt it is always safer to start with a soothing rather than stimulating remedy and not to apply the latter until improvement under the soothing agent has come to a standstill.

(a) Pastes: Pastes with a fatty base should be used only when the surface to which they are to be applied is dry enough for them to stick. They are applied to the lesion as butter is spread over bread.

The chemical reaction of the application is probably of greater significance than has heretofore been surmised. It may explain why one of these salves may aggravate a condition that is soothed by another one. Certain infantile eczemas have been found strongly alkaline, while some cases of eczema in adults were acid. It may be that the acidity of the sweat causes the more superficial lesions to be acid, while the alkalinity of serous exudates may be responsible for alkaline reaction in more deeply located lesions. The N. F. Soft Zinc Paste (Unna's), essentially Lime Liniment (linseed oil and lime water, equal parts) with zinc oxide and chalk (equal parts) to secure a soft pastelike consistency has an alkaline reaction. Of firmer consistency is Zinc Paste (Lassar's), which by reason of its 2 per cent of salicylic acid has an acid reaction and exerts a mildly stimulating effect toward healing. It can be made still firmer, yielding a better crust, by substituting hydrous wool fat for one half of the petrolatum (prescription 3). In this prescription, Coal Tar, which is alkaline, has been incorporated instead of the salicylic acid. A thin crust should be applied when a drying effect is desired, a thick crust when one wishes to soften and macerate. Such a crust may be best kept in place by means of a thin sheet of cotton and a bandage. Before a fresh application is made, the old one is removed with petrolatum or oil, provided it comes off readily. If not, it is left in place. Water should not be employed to remove it.

(b) Ointments: These have a softening effect as compared with pastes and they are indicated when the affected surface has become dry and is inclined to crack. Zinc salve may be used or a calamine zinc salve (prescription 4) if a somewhat flesh-colored zinc salve be desired, as for eczema of the ears.

When there is much itching, resorcinol 1 or 2 per cent or menthol (not above 2 per cent) may be added to Ointment of Rose Water (prescription 5), which by reason of the water it contains has a cooling and somewhat antipruritic effect of its own.

PRESCRIPTION 3.—Zinc Paste with Wool Fat

R Coal tar.....	1.00 cc.
Zinc oxide.....	
Starch	
Hydrous wool fat.....	
Petrolatum.....	12.50 Gm.

Apply as a rather thick crust and dust freely with talcum powder.

PRESCRIPTION 4.—Calamine Zinc Salve

R Calamine	4.00 Gm.
Zinc oxide ointment.....	30.00 Gm.

Apply twice daily.

PRESCRIPTION 5.—Ointment of Rose Water with Menthol

R Menthol	0.60 Gm.
Ointment of rose water.....	30.00 Gm.

Apply to itching part as required.

Chronic Stage.—In the chronic stage, stimulating (irritative) applications are indicated, and their strength should be in proportion to the chronicity of the condition. To be on the safe side, one may start with a mild application; but if no result is secured one should not hesitate to double or quadruple the strength. If excessive irritation occurs, one should promptly change to an appropriate soothing application, whereupon healing may take place that, without the interlude of irritation, might not have occurred.

(a) Lotions: These are especially suitable for application to extensive areas. A good example of a stimulating lotion is the Coal Tar Solution of the National Formulary. It is generally best to prescribe this lotion to be diluted by the patient, possibly with 20 parts of water to start with, and have him progressively double the strength. In some cases, even full strength may be tolerated with benefit. If one cannot rely on the patient's intelligence to carry out such instructions, a dilution of definite strength (prescription 6) had better be prescribed. It may afford great relief of the itching, and at the same time stimulate healing. A paste dressing might be applied over night.

PRESCRIPTION 6.—Diluted Coal Tar Solution

R Coal tar solution.....	30.00 cc.
Glycerin	8.00 cc.
Solution of calcium hydroxide.....	60.00 cc.
Water.....	to make 180.00 cc.

Apply three or more times daily.

(b) Ointments: These are preferably medicated with reducing agents, as such bodies stimulate the formation of horny epithelium (keratoplastic action). Most popular among these are the tars and sulphur.

Tars. Among the tars, the choice would lie between Wood Tar (which is acid), Oil of Cade (a tar prepared from juniper wood, which has the least unpleasant odor), Coal Tar (which is alkaline) and Sulphurated Bitumen (ichthyol), which is also alkaline and contains a considerable amount of sulphur. From 5 to 50 per cent of any one of these added to an ointment base may secure the desired degree and kind of stimulation. The tars are contraindicated in hairy places because of their tendency to produce folliculitis (tar acne).

Tar derivatives, less offensive because colorless and odorless, are of similar value. Most prominent among

these are resorcinol and salicylic acid. Resorcinol (prescription 7), which has considerable antipruritic value, may be employed for purpose of stimulation in a strength of from 5 to 20 per cent. In the higher concentrations it causes peeling of the skin (discutient effect). It may be incorporated in a paste base if pro-

PRESCRIPTION 7.—Resorcinol Salve

R Resorcinol	1.50 Gm.
Hydrous wool fat.....	10.00 Gm.
Petrolatum	20.00 Gm.

Apply locally with friction.

tection and maceration are desired. As it has a tendency to darken, it should not be used on the scalp. The brown stain produced by it on the clothing or the skin, may be removed by citric acid solution. Salicylic acid is devoid of any staining tendency and in strengths of 10 per cent (prescription 8) is a good discutient.

PRESCRIPTION 8.—Salicylic Acid Ointment

R Salicylic acid.....	3.00 Gm.
Hydrous wool fat.....	15.00 Gm.
Petrolatum	15.00 Gm.

To be rubbed in twice daily (in squamous eczema of the hands or feet).

Sulphur is perhaps especially indicated by skin with a seborrheic greasy tendency. Its strength may range from 3 to 30 per cent according to the tolerance of the lesion. The official Sulphur Ointment is 15 per cent in strength. The ointment base in which it is incorporated may vary from Benzoinated Lard, if a relaxant effect is desired, to Zinc Paste, if a protectant crust is aimed at.

PRESCRIPTION 9.—Film for Obstinate Itching

R Oil of cade.....	3.00 cc.
Flexible collodion.....	30.00 cc.

Paint on lesions.

PRESCRIPTION 10.—Film for Thickened Epidermis

R Salicylic acid.....	3.00 Gm.
Flexible Collodion.....	30.00 cc.

Paint on two coats twice daily until peeling occurs.

(c) Films: For obstinate itching (prescription 9) or to secure peeling of excessively thickened epidermis (prescription 10), films are useful.

(d) Irradiation: While contraindicated in acute cases, irradiation is useful in the chronic stage. Ultra-violet rays are believed to be especially valuable in cases associated with bacterial infections. General exposure to one erythema dose, with a second degree erythema dose to the affected area, may be given two or three times weekly. Roentgen rays often give spectacular results in subacute and chronic cases. They are usually given in fractional doses, 75 roentgens, at intervals of a week, carefully kept below an erythema dose. Radium is especially valuable in locations difficult to treat by roentgen rays, as in the treatment of fissured, crusted or lichenified patches. As the skin treated with x-rays and radium undergoes more or less permanent changes, their rather spectacular effect should not be resorted to until after the cause has been identified and removed. Resorting to this treatment repeatedly to remedy recurrences may result in dire damage to the skin.

Only soothing or at most but mildly stimulating applications are admissible in connection with radiation treatment.

CONSTITUTIONAL TREATMENT

If causal systemic treatment (q. v.) is not required, and even when it is, one may employ:

(a) Restorative Therapy: In the presence of anemia iron may be used or, to improve nutrition, cod liver oil.

(b) Alterative Therapy: Alkalis (potassium citrate or acetate) enough to alkalinize the urine may be useful in acute stages. Arsenic, while contraindicated in the acute form, may be useful in chronic cases characterized by dryness and thickening of the skin.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS ADOPTED THE FOLLOWING REPORT

H. A. CARTER, Secretary.

HYPERPYREXIA PRODUCED BY PHYSICAL AGENTS

Recently a survey of hyperpyrexia produced by physical agents has been carried out by the Council on Physical Therapy, requiring a period of about five months. The object of the survey was to evaluate the efficacy and to determine the dangers connected with the production of fever by physical agents. A list of questions was sent to physicians who have published articles on the subject of hyperpyrexia or have in some way been familiar with the subject. Thirty-four replies were tabulated.

Number of Physicians Reporting Who Have Given Artificial Fever Therapy

For six years	3
For five years	3
For four years	9
For three years	12

Several sources of energy were reported as having been tried; for example, diathermy, radiant energy, hot water baths, and various sources of high frequency current. Many physicians employed more than one source of energy.

Of this group questioned, more physicians made use of diathermy than any other method. Radiothermy, produced by either tubes or spark gap, came next. Radiant heat, infra-red cabinets, hot water baths, electric blankets, electric light cabinets, so-called nebulized spray cabinets or steam baths, electromagnetic induction and air conditioning came in the order named. One investigator reported the use of paraffin baths. Another reported giving hyperpyrexia by means of wrapping the patients in blankets and using no other source of heat except hot fluids administered by mouth.

The evidence presented did not indicate the number of patients treated by the various methods. It would appear, however, that more patients have been treated by diathermy than by any other method.

More patients afflicted with dementia paralytica were treated than any other disease mentioned. Multiple sclerosis came next, and then in order syphilis, chronic arthritis, asthma, tabes, gonorrhea, gonorrheal arthritis and circulatory disturbances of the extremities.

The work that has been done up to this time indicates certain definite clinical possibilities; however, the lack of statistical evidence does not warrant publishing the therapeutic possibilities or indications.

Fifteen of the thirty-four physicians reported untoward results, while seven replies on this question were too indefinite to tabulate. Thirteen reported burns, most of them being minor burns and due predominantly to the use of electrodes in the diathermy

treatment. Some reported burns on the skin surface caused by local action of the high frequency electric field. One investigator stated nothing serious. Six physicians reported that untoward results were due to the technic used. Another reported the untoward results due to faulty judgment and another to the effect of too rapid rise in temperature. In the set of questions sent out to physicians, one asked for the number of patients treated and another for the number of deaths traceable to the treatment of hyperpyrexia by physical agents. A total of forty-eight hundred and nine patients were treated by thirty-four physicians. Twenty-one physicians reported no deaths, while thirteen reported twenty-nine deaths.

One physician reported that out of seven deaths attributable to the treatment given he believed quite definitely that four were due to the humidity in the infra-red cabinet as a complicating factor. One physician reported that two deaths occurred as the indirect result of treatment.

One question asked was whether any complications had been observed, for example, in the cardiovascular system, genito-urinary system and nervous system. Nearly all the physicians reported that they had no complications. However, several did report heat stroke, circulatory collapse, herpes of the cornea, cerebral hemorrhage, albuminuria, tetany and convulsions.

Physicians reported that complete examination was always given to the patient and that any patients with cardiovascular diseases were not given the treatment.

After a careful study of this survey it appears that any type of machine or apparatus may be used with equal success, provided the person in charge is thoroughly competent and the technician under him is attentive and well informed as to the facts and dangers involved. The Council believes that the technic and administration of this treatment should be given as much study as a surgeon gives to a specialty or a certain branch of surgery. It is probable that any good scalpel will render efficient service in the hands of a skilful surgeon but would be a highly dangerous instrument in the hands of one not proficient in its use.

The Council believes that to subject a patient to an artificial fever of from 105 to 106 F., sustained for five hours or more, is to subject him to a fairly strenuous cardiovascular functional test. Patients with normal heart, kidneys and blood vessels tolerate it well, but patients with myocardial degeneration or with valvular, coronary or other cardiac abnormalities, with impaired renal function from organic disease, with excessively high blood pressure or arteriosclerosis, or with tuberculosis, diabetes or far advanced syphilis of the central nervous system (late, rapidly progressing neglected cases or patients who are totally demented) do not tolerate such treatment well and should not be subjected to it.

CONTRAINDICATIONS

For the reasons given, advanced age (with a few exceptions 60 years may be taken as an arbitrary limit), cardiac or renal insufficiency, rheumatic endocarditis, aortic aneurysm, advanced arteriosclerosis, pulmonary tuberculosis, diabetes, and late neglected neurosyphilis that has progressed to complete dementia should be regarded as absolute contraindications.

In selecting patients for artificial fever therapy, therefore, more than casual attention must be given to such complications. Otherwise, unnecessary fatalities may occur.

PRELIMINARY STUDY

Every patient should undergo a thorough physical examination and clinical investigation. The following laboratory studies should be made:

Electrocardiogram

In patients suffering from infections or gonorrheal arthritis, a thorough roentgenographic examination should be made

Complete blood count before and after each session of treatment

Sedimentation time

Coagulation time

In syphilitic patients, besides the foregoing, a Wassermann test, Kline test, Kahn test, globulin test, colloidal gold test, cell count, and protein determination of spinal fluid

The Council on Physical Therapy, after studying this problem, realizes that this preliminary survey is far from complete. However, the survey does show that the treatment of disease by means of hyperpyrexia is now established but that the best method for administering artificial fever induced by physical agents that can be employed with safety, convenience and comfort to the patient and is subject to complete control by adequately trained physicians is not firmly established. The Council believes that this method should be used only in hospitals, surrounded with the safeguards commonly employed in a major surgical operation and under the direction of skilled physicians. The assisting technician should have ample training and experience and must be capable of recognizing untoward symptoms and know ways of avoiding dangers

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

DEXTROSE (See New and Nonofficial Remedies, 1934, p 270).

The following dosage forms have been accepted:

Solution Dextrose U. S. P., 25 Gm., 50 cc., in Bottles. Each bottle contains dextrose U. S. P., 25 Gm., in sufficient distilled water to make 50 cc.

Prepared by the Cutter Laboratory, Berkeley, Calif.

Solution Dextrose U. S. P., 50 Gm., 100 cc., in Bottles. Each bottle contains dextrose U. S. P., 50 Gm., in sufficient distilled water to make 100 cc.

Prepared by the Cutter Laboratory, Berkeley, Calif.

Solution Dextrose U. S. P. 5% in Saffi-flask Containers. Each Saffi-flask contains 1,000 cc of a solution containing 52.5 Gm of dextrose U. S. P.

Prepared by the Cutter Laboratory, Berkeley, Calif.

Solution Dextrose U. S. P. 10% in Saffi-flask Containers. Each Saffi-flask contains 1,000 cc of a solution containing 105 Gm of dextrose U. S. P.

Prepared by the Cutter Laboratory, Berkeley, Calif.

RABIES VACCINE (See New and Nonofficial Remedies, 1934, p 378).

The National Drug Co., Philadelphia

Rabies Vaccine (Human), (Chloroform Killed).—V. D. Co.—Antirabic vaccine prepared according to a modification of the method of David Semple (chloroform killed). The brains and spinal cords of rabbits killed on the sixth or seventh day after inoculation with fluid rabies virus are ground with physiologic solution of sodium chloride containing 2 per cent chloroform, to yield a 25 per cent suspension of brain and cord substance. The suspension is then placed in the refrigerator at 2 to 5 C for two months. It is then tested for absence of living virus by rabbit injection. The finished product represents a 25 per cent emulsion.

Marketed in packages of fourteen vials, each containing a dose of 0.5 cc, and in packages of fourteen syringes, each containing a dose of 0.5 cc.

ORTAL SODIUM (See THE JOURNAL, March 24, 1934, p 928)

The following dosage form has been accepted

Capsules Oral Sodium $\frac{3}{4}$ grain (0.05 Gm.)

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

"VITA-CELL" NOT ACCEPTABLE FOR N. N. R.

Under the uninformative proprietary name "Vita-Cell" Godissart and Pyles, Hollywood, Calif., market a series of products: Vita-Cell—Surgical, Vita-Cell—Dental, Vita-Cell—Home Treatment, Vita-Cell—Dental Plastic, Vita-Cell—Ointment, Vita-Cell—Soap. The firm presented these products for consideration by the Council.

Vita-Cell is claimed to be "A Superior Antiseptic, Deodorant and Healing Agent." The advertising circular states: "VITA-CELL is the result of years of research by the Medical Profession and chemists of Europe, and more recently by dentists and physicians of the United States. A new principle of therapeutics has been evolved and its application perfected the result VITA-CELL." This is typical of the advertising propaganda for the product. In submitting the product to the Council the firm stated:

"For purely commercial reasons, we are reluctant to offer, at this time, a quantitative statement of composition."

As Vita-Cell is a secret formula, a statement of the process of manufacture must necessarily be limited."

The Council, of course, cannot consider the acceptance of a product of secret composition.

Although at various places in the advertising it is stated that "Vita-Cell" is not intended as a "cure-all," throughout the advertising the product is recommended in a host of conditions, from "athlete's foot" to venereal infections. As evidence to support these multitudinous claims, the firm submitted a case report from The All Nations Clinic, Los Angeles, and ten letters from physicians, dentists and an animal pathologist, which are in effect no more than testimonials and are of no value as controlled scientific evidence. The extensive therapeutic claims for the product may therefore be said to be almost entirely unsupported.

If "Vita-Cell" were the "result of years of research" which the firm's advertising claims it to be, it is needless to point out that there would not be lacking in medical literature reports on its composition and probable or actual therapeutic value. No such reports are known to the Council, and the firm has failed to call attention to any such if they do exist. The "Vita-Cell" Dental XX Home Treatment package and circular are obviously directed to the general public, which is in direct contravention of the Council's rules. The danger of indiscriminate reliance of the public on this preparation for all the conditions for which it is claimed to be of value is too obvious to need further discussion.

The Council declared "Vita-Cell" and the submitted forms under which it is marketed unacceptable for New and Nonofficial Remedies, because the preparation is of secret composition and is marketed under an uninformative proprietary name with exaggerated and unwarranted therapeutic claims in such a way as to lead to its ill advised use by the public.

When the foregoing was sent to Godissart and Pyles, the firm replied that it had "abundant evidence to confirm all our claims" and promised to "make clinical control tests in the manner prescribed by your Council of Therapeutics if you will be kind enough to describe to us the technique you desire." The Council holds the burden of proof for such claims to lie justly on the firm which makes them. The firm has not submitted any evidence for the therapeutic value of "Vita-Cell" and "Vita-Cell" preparations other than that already found unacceptable by the Council. No quantitative statement of composition has been submitted.

Before receiving the Council's report, the firm had informed the Secretary that a revision of labels and advertising in conformance with the suggestion of the Department of Agriculture was contemplated. After considerable correspondence the firm submitted some "revised" labels and cartons. These are essentially as objectionable as those submitted before.

In view of the firm's failure to make the products acceptable, the Council voted to confirm its rejection of "Vita-Cell" and the submitted "Vita-Cell" preparations.

SATURDAY, OCTOBER 27, 1934

"DOCTORS, DOLLARS AND DISEASE"—RADIO EDUCATION OR PROPAGANDA

In 1929 a series of meetings called by the American Association for Adult Education resulted in the formation of a body known as the National Advisory Council on Radio in Education, Inc. Its general purpose is said to be to "further the development of the art of radio broadcasting in American Education." Recently, Congress enacted some legislation entitled "The Federal Communications Commission Act," which automatically abolished the Federal Radio Commission. This act also makes it mandatory on the new commission "to study the proposal that Congress by statute allocate fixed percentages of radio broadcasting facilities to particular types or kinds of nonprofit radio programs" and to report to Congress by Feb. 1, 1935.

The National Advisory Council on Radio in Education, Inc., is exceedingly interested in this problem, because it has made education of the public over the radio its particular province since the time of its organization. The Council wants more time on the air for education. In a recently issued circular, the director says "The council is an organization independent of faction, nonpartisan in its procedure, disinterested as to personnel and noncommercial in operation." Notwithstanding these assertions, the medical profession is now confronted with the promotion by the National Advisory Council on Radio in Education, Inc., of a series of broadcasts under the title "Doctors, Dollars and Disease," said to be presented by the Public Health Committee of the National Advisory Council on Radio in Education, Inc. These programs are offered every Monday evening over WABC, Columbia network, extending from coast to coast, at 7:45 Pacific time, 8:45 Mountain time, 9:45 Central time, and 10:45 Eastern time.

Let us then view the nature of the organization of the Public Health Committee which prepared the program and the nature of the program itself to see to what extent the National Advisory Council on Radio in Education, Inc., has fulfilled its claims of being inde-

pendent of faction and nonpartisan in procedure. The Public Health Committee includes as its chairman William Trufant Foster. This is the same Foster, an economist and not a physician, who attacked organized medicine bitterly at a conference held in Philadelphia last February, fully reported in THE JOURNAL, March 3, page 701. Associated with Mr. Foster on this committee are the following physicians: Ray Lyman Wilbur, chairman of the Committee on the Costs of Medical Care and signer of its majority report, Thomas Parran Jr., health officer of the state of New York, committed in repeated addresses to compulsory health insurance and measures leading to the socialization of medicine; Haven Emerson, formerly a president of the American Public Health Association and a signer of the majority report. Included with these four are Alice Hamilton, a distinguished investigator in industrial diseases, whose writings indicate nevertheless that her pity for the sad fate of the majority of mankind overbalances her scientific judgment in matters of social control, and, last of all, Dr. Hugh S. Cumming, surgeon general of the United States Public Health Service. It will be obvious to any one that this Public Health Committee of the National Advisory Council on Radio in Education, Inc., is overwhelmingly controlled by the state medicine and socialization of medicine points of view, and that it contains no definite representative of the 100,000 physicians organized as the American Medical Association.

The radio program developed under the auspices of this committee is, as might have been expected, overwhelmingly for the socialization of medical care. It contains the name of but one person who signed the minority report of the Committee on the Costs of Medical Care, and there are indications that he accepted under a misapprehension as to the nature of the program and will not appear. Those who are to discuss the future of medical care and the subject of medical economics are for the most part nonmedical men, unfamiliar with medical practice and for the most part definitely opposed in their writings to the policies of organized medicine. Representing the opposite point of view are Walter P. Bowers, editor of the *New England Journal of Medicine*, who has made that periodical largely the organ of the majority report of the Committee on the Costs of Medical Care, Thomas Parran, George H. Bigelow, Haven Emerson and Ray Lyman Wilbur, who speak as physicians on this program. These are, all of them, proponents who would change seriously the nature of medical practice. Among the laymen listed are such well known names as Edward A. Filene, Michael M. Davis, C. Rufus Rorem, Nathan Sinai, I. S. Falk, Edgar Sydenstricker and Harry H. Moore. It calls the roll of the agitators from the Committee on the Costs of Medical Care. Other speakers include Foster, Paul H. Douglas of the Uni-

versity of Chicago, Robert Jolly of Houston, Texas, and Livingston Farrand, president of Cornell University, the latter as an M.D., who has for long been somewhat out of touch with medical affairs.

It should be clear to any physician that this program indicates an attempt on the part of the interests represented in the majority report of the Committee on the Costs of Medical Care to further its propaganda. In developing a program of this type the National Advisory Council on Radio in Education, Inc., has been untrue to the principles on which it was established. Thereby it fails to merit support from the medical profession. Nevertheless, physicians will do well to be aware of the matter and to use such influence as they may possess with the radio stations that carry such material to bring about a realization of its true nature.

It might have been within the province of the National Advisory Council on Radio in Education, Inc., to develop a series of useful lectures on the prevention of disease and on the maintenance of health. It might have used some of the time, which apparently it is able to get without charge from the broadcasting chains, for the enlightenment of the public on many of the scientific fallacies promoted by commercial interests. It has, however, failed to avail itself of these opportunities, devoting itself and its time instead to what constitutes essentially an undermining of the medical profession of this country. It would be interesting to know the motives that animated the executive officers of the National Advisory Council on Radio in Education, Inc., to lend themselves to this propaganda.

LATENT AND ARTIFICIAL IMMUNIZATION AGAINST DIPHTHERIA

Until recently the British navy maintained in London a semiclosed school of boys, the Greenwich Hospital School, which offered an unusually favorable opportunity to study infection and immunization in diphtheria. Full advantage has been taken of this opportunity, as shown by the recent report¹ on the results of studies that were made. From 1921 to 1928, tests for Schick immunity were carried on regularly but artificial immunization was not practiced, while from 1928 to April 1933, artificial immunization was practiced. Consequently clinical and carrier infection as well as latent immunization could be studied by the same methods under natural and artificial immunity.

By latent immunization is meant the appearance of specific diphtheria antitoxin, in the blood due only to environmental circumstances, presumably subclinical and carrier infection with diphtheria bacilli. It must be understood clearly that while the operation of certain

racial and genetic factors cannot be excluded in latent immunization, this antitoxin is not inborn but the product of antigenic stimulation by diphtheria toxin. In the Greenwich Hospital School it was found that under natural conditions (1921-1928) from 30 to 40 per cent of groups of Schick reactors became latently immune in the course of four months when the prevalence of diphtheria in the school was high; furthermore, that the spread of latent immunity bore a close relation to the seasonal variation in clinical diphtheria, there being much more immunization in the winter than in the summer months. These observations establish again and clearly the development of latent immunization and Schick immunity as diphtheria spreads in an unprotected community. The results of various types of specific prevention of diphtheria in the Greenwich Hospital School may be summarized briefly as follows: The induction of a negative Schick test—Schick immunity—by artificial means gives practically complete protection against clinical diphtheria in the protected individuals but has no preventive influence on symptomless or carrier infection, which on the contrary actually is increased. In other words, active immunization against diphtheria as now practiced with toxin-antitoxin or some form of toxoid does not prevent but tends to increase carrier infection with diphtheria bacilli. From this important fact, which is supported by ample and convincing evidence, it follows that in a given community incomplete immunization may be followed by increase in clinical diphtheria in case the susceptible, unprotected portion outnumbers the protected. The apparent failures of certain antidiphtheria campaigns are explainable by this circumstance, which also makes it clear why it is essential to immunize children in the preschool years. Incomplete immunization may increase the risk of infection proportionately more than it increases the herd immunity. Again, while artificial prevention may protect the individual, he may become a potential danger in the home or group where there are susceptibles. How is this paradox to be explained that specific prevention may protect the individual and yet be the means of spreading the infection? Simply on the ground that the symptoms of diphtheria are caused by the exotoxin of the diphtheria bacillus, and it is the exotoxin that is neutralized by the antitoxin called forth by the injection of the antigenic toxin or toxoid. The immunity in diphtheria is antitoxic, directed against the toxin, rather than antibacterial and directed against the bacillus itself. Without the action of the toxin the main pathogenic agent in diphtheria, infection with the diphtheria bacillus, is of little significance and virtually symptomless.

Precisely similar conditions obtain in scarlet fever, in which the essential immunity and protection also depend on specific antitoxic action. There is, however, no evidence at hand to indicate that the toxin of the scarlet fever streptococcus toxin has been changed to

1. Dudley, S. F.; May, P. M., and O'Flynn, J. A.: *Active Immunization Against Diphtheria: Its Effect on the Distribution of Antitoxic Immunity and Carrier Infection*, Medical Research Council, Special Report Series, No. 195, London, 1934.

toxoid like the diphtheria toxin. The Schick test in diphtheria and the Dick test in scarlet fever are each dependent on the respective antitoxins in the blood.

Among other interesting observations by the English investigators may be noted the facts that tonsillectomy lowers carrier infection and that there appears no great difference between the different types of diphtheria bacilli as immunizing agents. Their observations and comments on immunity against diphtheria toxin, Schick immunity, are of special interest. This immunity may not be permanent, but nevertheless a degree of protection may persist because the body once subjected to the antigenic toxin will respond with increased promptness and range to renewed antigenic stimuli. This deduction is in full harmony with a principle of immunity. Fortified by reinfection from the environment the immunity may become permanent, but immunizability and durability of immunity vary depending on genetic make-up and environmental experience. On the whole the diminution or loss of Schick immunity is regarded as of small consequence. The conception of the interaction between latent and artificial immunization against diphtheria toxin and thus against diphtheria are stated well in this quotation (p. 98): "Although an artificial immunizing agent may be too weak to produce a durable Schick immunity unaided by latent immunization, the artificial agent may act as a primary sensitizing stimulus to those who are about to receive further stimuli from the natural immunizing influences in a diphtherial environment."

Finally a word on the epidemiology of diphtheria as illustrated by the noteworthy study under consideration: In the conditions of herd immunity and herd infection here studied so closely one cannot but be impressed with the tendency of host and parasite to mutual adaptation. When the prevalence of diphtheria increases antitoxic immunity rises, and as the incidence falls the susceptibility increases. The reaction of parasite and host on each other prevents destruction of either by the other and determines the amount of diphtheria at any time and place.

EXTRAMEDULLARY HEMATOPOIESIS IN MAN

One of the most striking examples of the "safety devices" for insuring the adequate functioning of vital tissues in times of stress is the protective mechanism that operates to maintain a sufficient quantity of circulating red blood cells. A sudden loss of blood, for example, is compensated for by the rapid release from the bone marrow of immature erythrocytes, by the reticulocytes, and by an outpouring of stored red cells from certain reservoirs. If the blood loss is more severe or prolonged, the erythrocytic marrow itself may hypertrophy within its bony casing, more or less completely replacing the fatty marrow within a short time. Spicules of bone or even the inner portions of the bone

shaft may disappear, apparently to provide additional space for the expanding red marrow. If these adjustments still fail to meet the demand for increased erythropoiesis, blood production in other tissues may take place. The phenomenon of extramedullary hematopoiesis is particularly pronounced in pathologic processes in which the marrow tissue is damaged or is replaced by a malignant growth. Usually under these conditions the process of blood formation is taken over more or less directly by the primitive erythrocytic tissues, namely the spleen, the principal blood producing organ during the fetal period, and the liver, the erythropoietic organ of the embryo. However, myeloid metaplasia frequently occurs in other tissues or organs, such as the kidneys, lymph nodes, suprarenals, thymus, pleura, falx cerebri and the broad ligaments, or in adipose tissue.

Clinically, extramedullary hematopoiesis apparently takes place more frequently than has been generally supposed. Although a few reports of extramedullary blood formation in certain types of anemia and leukemia have appeared in the literature during the past decade, general recognition of the phenomenon is comparatively recent. Extensive ectopic hematopoiesis was reported several years ago¹ in a case of von Jaksch's anemia in an infant. Large, tumor-like masses of hematogenic tissue were found in several tissues, particularly in hili of the kidneys. Similar observations were made in an adult with anemia due to chronic hemorrhage; widespread extramedullary hematopoiesis was observed, in addition to distinct hyperplasia of the bone marrow. More recently,² extramedullary erythropoiesis was reported in two cases of severe anemia resulting from a damaged bone marrow. In one case, active blood formation in the lymph nodes followed atrophic changes in the myeloid tissue of the bone marrow and spleen. In the other subject, a case of metastatic adenocarcinoma of the prostate associated with almost complete replacement of the bone marrow and lymph nodes, vigorous blood formation occurred in the spleen. The foregoing clinical cases afford a convincing demonstration of the ability of the embryonic and fetal blood forming tissues even in adult life to resume their primitive functions in order to compensate for a loss of other myeloid tissue.

The histogenic processes involved in the establishing of extramedullary erythropoiesis are not well understood. Some information of value in elucidating the problem has been obtained in a current study on the transformation of adipose tissue into hematopoietic tissue.³ Apparently the parent cells, having the appearance of small lymphocytes, may originate from the local stromal cells or perhaps may represent migrants from

adjacent lymphatics. These cells accumulate in certain areas about the capillaries and develop into typical hemocytoblasts, which, according to the theory endorsed by Jordan, migrate into the adjacent capillary and finally differentiate into mature erythrocytes.

Thus, at the present time there is unfolding another fascinating story of processes that enable the human organism to survive adverse circumstances.

Current Comment

THE DOCTOR AND THE LEGISLATOR

Next week physicians throughout the country will be voting for men who will represent them in the next Congress. They will in many places be expressing their approval also of candidates for legislative, judicial and executive offices in various state and minor divisions of our government. The time has come when it is desirable for every man to express himself definitely by the ballot and in other ways on the nature of our government. There are indications that plans are being developed for new legislation leading to modifications in the form of medical practice, varying from compulsory health insurance to complete state medicine. Again and again it has been said that physicians exercise a powerful influence, owing to the support which is obtainable from those to whom they have given professional ministrations. It is important that they utilize such influence in maintaining medical practice at the professional level which it has reached in this country—a level which is higher than that of any other country in the world and which at the same time gives to the average American a better quality of medical service than is given to the average man in any other nation. Recently in private conversation and in other ways several of the leading statesmen of this country have indicated to executives of the American Medical Association that there is just one way in which the average citizen may make his influence definitely felt in relationship to proposed legislation; that is, to bring his opinion and that of his associates directly to the legislator. Senators and congressmen equally are influenced by letters from their constituents and by messages from well established organizations indicating their point of view. No one knows at this moment just what type of legislation will be advanced by the administration itself in relationship to these matters, nor is there any definiteness concerning proposals which individual legislators may advance on the urging of interested bodies. Physicians will be kept informed of proposed legislation through *THE JOURNAL* and through the *Bulletin of the American Medical Association*. It is important that they know now the points of view of the legislators to whom they give their support and that they inform such legislators, when elected, of their feelings in regard to such social legislation as may come before the next Congress. Such positive action should yield definite results.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be as follows:

- November 1. The Common Drinking Cup, W. W. Bauer, M.D.
November 8. Your Child's Sleep, W. W. Bauer, M.D.
November 15. The Health Audit, W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

- October 30. Diphtheria Must Go, W. W. Bauer, M.D.
November 6. The Fight Against Appendicitis, W. W. Bauer, M.D.
November 13. Does Medicine Cost Too Much? Morris Fishbein, M.D.

ARKANSAS

Investigation of Eclectic Diplomas and Licenses.—Officials have been cooperating with the Eclectic State Medical Board of Arkansas in an investigation of the issuance of fraudulent diplomas and the irregular licensure of eclectic physicians in Arkansas. With the focus of the investigation apparently on graduates of the Kansas City College of Medicine, the charter of which was revoked in 1926, reciprocity licentiates from eclectic boards in other states are also under inquiry. At present, Arkansas is the only state having an eclectic board. The licenses of the following persons were revoked at a recent meeting of the board for the reasons indicated:

J. Sidney Pierce, Little Rock, conviction on charges involving moral turpitude.

Auxenty Miroch, Bloomfield, Va., fraudulent credentials.

William S. Dews, Wynne, fraudulent credentials.

Erick F. Ebert, St. Louis, fraudulent credentials.

Lee Fisher, Little Rock, fraudulent credentials.

Harold S. Bayless, address unknown, fraudulent credentials.

The license of Charles Wade Page, Banks, was revoked on a charge of its having been obtained by fraud and deception. The testimony revealed that Page also had licenses under the names of Charles Russell Conway and Charles William Pagel; these licenses also were revoked. Records indicate that, in 1915, Charles William Pagel, following the revocation of his Indiana and Illinois licenses for forgery and immoral acts, was arrested as the alleged head of a gang of automobile thieves. In 1918, Pagel had his name changed officially to Charles Russell Conway. Later a report came announcing the death of Charles Russell Conway, Greensburg, Ind., at La Ceiba, Honduras, C. A., Dec. 29, 1921. The recent investigation has revealed this report to be false. In the interim, one Charles Wade Page

had been licensed in Florida in 1919, claiming graduation from a Missouri eclectic school. This license was revoked in 1930 following the charge of "stealing an automobile." On this charge he was given a five year sentence to the Florida State Farm at Raiford. After serving little more than a year he was given a pardon on condition that he leave the state. In 1924, Page was licensed in Arkansas, claiming graduation from the American Medical College, St. Louis, in 1902. When a newly appointed board began checking its licentiates and called for reregistration, the discrepancies were noted. Subsequent investigations revealed Page, Conway and Pagel to be the same person. Pagel was listed "address unknown," but Page and Conway were located, according to the records, at Banks and New Edinburgh. Records show that as Pagel he graduated from the American Medical College, St. Louis, in 1896. Ali Yhia Debeh, faced with a similar charge, did not appear, but was represented by an attorney who asked for a continuance since Debeh could not be located. The license was revoked on the testimony presented, but this action of the board was later enjoined by the court. Dews testified that negotiations which he had with one George M. Lindsay, Kansas City, Mo., "developed into the procuring of a diploma in the Kansas City College of Medicine and Surgery, Kansas City, Mo., and a license to practice medicine in the state of Arkansas." For these, Dews is said to have given Lindsay \$500 with a promise of an additional \$1,500 at some future date. Dews stated that he had two years in the "University of Illinois at Jacksonville, Illinois." Paul D. Wesson, Hazen, who pleaded guilty to violating the Harrison Narcotic Act, was placed on probation for six months. Date R. Alexander, the founder of the Kansas City College of Medicine and Surgery in 1915 and the former dean of the Eclectic Medical University of Kansas City, testified at the trials, stating that these men had never attended the Kansas City College of Medicine and Surgery; that he had never seen them before and that the credentials in their possession were forged. A resolution was adopted at this meeting of the board to continue to investigate all licentiates who had obtained their license by fraudulent methods, and those who were chronic inebriates or addicted to the use of narcotics.

CALIFORNIA

Southern California Meeting.—The Southern California Medical Association will hold its next semiannual meeting in Los Angeles, November 2-3. Dr. Laurence Selling, clinical professor of medicine, University of Oregon Medical School, Portland, will be the guest speaker. He will deliver his paper Friday evening on "Diagnosis of Epilepsy." Other speakers will be:

- Dr. Cullen Ward Irish, Cerebrovascular Lesions, a Clinical Pathologic Survey.
- Dr. Arthur E. Guedel, Apnea Under Anesthesia.
- Drs. Nelson Paul Anderson and Samuel Ayres Jr., Diagnosis and Treatment of Common Skin Diseases in School Children.
- Drs. James F. Anderson and Bernard J. Hanley, Review of 190 Cases of Heart Disease Complicating Pregnancy.
- Dr. John L. Pomeroy, Public Health and Medical Coordination in Poliomyelitis Control.
- Dr. Egerton Crispin, Schüller-Christian's Disease (Lipoid Xanthomatosis).
- Drs. Francis M. Pottenger and Francis M. Pottenger Jr., The Supra-nal Hormones in Relationship to General Medicine.
- John F. Kessel, Ph.D., Dysenteries in Southern California.

All the speakers are from Los Angeles, except the Drs. Pottenger of Monrovia. A clinical pathologic conference will be held Saturday morning in the new unit of the Los Angeles General Hospital, under the direction of Drs. Newton G. Evans and Ernest M. Hall and members of the clinical staff.

Chiropractic-Physical Therapy Initiative.—A chiropractic-physical therapy initiative, to be voted on by the electorate, November 6, proposes to create a public corporation, the State Chiropractic Association, and to confer on a board of directors of that corporation exclusive jurisdiction over the practice of chiropractic and of physical therapy. Two types of licenses are to be issued by the board of directors: (1) a license to practice chiropractic; (2) a license to practice physical therapy. No person may obtain a license to practice physical therapy unless he first obtains a license to practice chiropractic. A chiropractic licentiate will be permitted to adjust "by hand to restore to normal any abnormal anatomic disrelation in the condition of human beings." A physical therapy licentiate will be authorized to practice obstetrics, to use, prescribe and practice prophylactic hygiene and sanitation and dietetics "including in any form, herbs, oils and all animal and vegetable foods," and to use all "systems, methods or instruments in diagnosis, including the use of Roentgen Rays." Such a licentiate, also, may employ electrotherapy, hydrotherapy, manipulative therapeutics, heat and light therapy, heliotherapy and mechanotherapy, in the treatment of physical or mental

conditions of human beings. The provisions of the California medical practice act are not repealed by the proposed measure "unless they conflict" therewith. Chiropractic and physical therapy licentiates will be permitted to practice in all institutions supported wholly or in part by public funds.

COLORADO

Society News.—The Denver Society of Internal Medicine presented the program before the Medical Society of the City and County of Denver, October 2; speakers were Drs. Clough T. Burnett on "The Congestive Heart," and Wilfred S. Dennis, "Xanthomatosis."—The medical care of families on federal aid in Long district, Weld County and Boulder County was discussed by Drs. Virgil J. Jernigan, Longmont, Myron W. Cooke, Erie, and Fred C. Klopfcstein, Boulder, before the Boulder County Medical Society in Boulder, October 11; Mr. C. H. Sievers discussed federal relief. Cases of ruptured appendix, sarcoma of the mediastinum and retroperitoneal sarcoma were presented by Drs. Oscar M. Gilbert, Boulder, and Willard J. White, Longmont.

CONNECTICUT

Personal.—Yandell Henderson, Ph.D., professor of applied physiology, Yale University School of Medicine, addressed the Brazilian Academy of Medicine in Rio de Janeiro, September 7, on "Asphyxia and Resuscitation." He also spoke at the opening of the new building of the Institute of Hygiene in São Paulo, Brazil, September 17, and gave an address before the local medical society, September 18.

Report on Tuberculosis Campaign.—Thirty-three cases of tuberculosis were found in the campaign to detect tuberculosis which was carried on during the past school year in Connecticut. According to provisional figures, there were 56,942 roentgenograms taken of school children in 142 towns. Of these, no evidence of tuberculous lesion was found in 54,376. Calcific or fibrocalcific deposits suggesting healed or healing primary tuberculous disease were found in 972, and evidence of pulmonary disease, probably active tuberculosis, in 33. This tuberculosis survey among school children was sponsored by the state health department, the state medical society, the state board of education and the state tuberculosis commission, with the cooperation of various local and state agencies. The state plan evolved from one carried out in New Haven under the auspices of the departments of health and education. Roentgenograms taken total about one sixth of the public school enrolment. The completion of the examination for diagnosis brings to a close the first procedure recommended by the state tuberculosis commission. The second will be a study of the patient's family to discover the source of infection in cases in which tuberculosis is found.

ILLINOIS

Credit Bureau.—At a meeting of the Peoria City Medical Society, September 5, it was voted unanimously to establish and maintain a medical business bureau. The bureau will be controlled by the society and managed by a special board named by the president, according to *Peoria Medical News*. Dues of the society have been increased from \$14 to \$15 a year to maintain the bureau.

Society News.—Dr. William R. Cubbins, Chicago, addressed the Rock Island County Medical Society, October 9, on "Fractures of the Lateral Condyle of the Tibia."—At a meeting of the Will-Grundy County Medical Society, October 10, Dr. Philip Lewin presented a paper on "The Classification, Etiology and Treatment of Arthritis."—Dr. Clarence O. Sappington, Chicago, addressed the Peoria City Medical Society, October 16, on occupational diseases.

Chicago

Discussion of Appendicitis.—The theme of the program of the Chicago Medical Society, November 7, will be a discussion of appendicitis. Speakers will be:

- Dr. Leroy H. Sloan, assistant clinical professor of medicine, Rush Medical College, Its Early Recognition in General Practice.
- Dr. John O. Bower, clinical professor of surgical research, Temple University School of Medicine, Philadelphia, Apparent Increase of Mortality Rate and Its Causes.
- Dr. Karl A. Meyer, medical superintendent of Cook County Hospital, Surgical Problems in Acute Appendicitis.

Society News.—At a meeting of the Chicago Pathological Society, October 8, Dr. Edwin F. Hirsch, among others, spoke on "Generalized Osteosclerosis with Chronic Polycythemia Vera." The presidential address was given by Dr. Isadore Pilot on "Hemolytic Streptococci, Their Present Status and Relationship to Certain Clinical Entities."—A symposium on collapse therapy was presented before the Chicago Tuberculosis

Society, October 11, by Drs. Frederick Tice, Allan J. Hraby, Karl J. Henrichsen, Robert F. Berry and Henry C. Sweany. —Dr. Traian Leucutia, Detroit, discussed "Further Contributions to the Problems of Superhigh Voltage Roentgen Therapy" before the Chicago Roentgen Society, October 11, and Dr. Benjamin H. Orndoff gave a report on the fourth International Congress of Radiology. —At a meeting of the Chicago Orthopedic Club, October 12, Dr. Arthur Steindler, Iowa City, among others, discussed "Tuberculosis of the Wrist." —Dr. Robert von der Heydt discussed "The Ageing Lens" before the Chicago Ophthalmological Society, October 15, among other speakers. —Dr. Leon Unger addressed the Chicago Society of Allergy, among others, October 15, on "Turpentine Abscesses in Treatment of Intractable Asthma." —Speakers before the Chicago Pediatric Society, October 16, were Drs. Arthur H. Parmelee on "Physiologic Changes of Adolescence" and Bert I. Beverly on "Psychologic Problems of the Adolescent." —"What Organized Medicine Has Done for Society" was the title of a public lecture by Dr. Morris Fishbein, editor of *THE JOURNAL*, October 18. The lecture, sponsored by the Jackson Park branch of the Chicago Medical Society, was given in the Hyde Park High School Auditorium.

Anniversary of Institute for Juvenile Research.—The twenty-fifth anniversary of the Institute for Juvenile Research was observed at the Medinah Club, September 28. Speakers included Dr. William Healy, director of the Judge Baker Foundation, Boston, on "What Twenty-Five Years Have Taught Us About the Problems of Childhood"; Dr. David M. Levy, formerly chief of staff, Institute of Child Guidance, New York, "Recent Trends in the Study of Behavior Problems"; Dr. Julius H. Hess, "Contribution of the Institute to Services for Children from the Medical Point of View," and Mr. Henry P. Chandler, authority on child welfare legislation, "The Place of Experts in Public Welfare." The Institute for Juvenile Research, the first child guidance clinic established in the United States, was founded in 1909 through gifts of Mrs. William F. Dummer and under the direction of Dr. Healy. At the end of the first five years, the financial support of the institute was assumed by the board of commissioners of Cook County and, when Dr. Healy left Chicago in 1917 to take charge of the Judge Baker Foundation, it was transferred to the state department of public welfare. At that time Dr. Herman M. Adler, now of Berkeley, Calif., became director and continued in that capacity until 1930, when Dr. Paul L. Schroeder became director of the institute. While the work of the institute was originally limited to the treatment of children brought before the Cook County Juvenile Court, during recent years the scope of its activities has been extended to agencies throughout the entire state. It is concerned with the examination of children who present problems of social adjustment, conduct or personality, and seeks to aid parents, teachers and social agencies in the better understanding and development of the child. In 1925, Dr. Adler organized the Behavior Research Fund which has functioned as an adjunct to the institute and carried on various research projects which could not be financed by state appropriations. Ernest W. Burgess, Ph.D., is director of the fund.

IOWA

Personal.—Dr. Carl L. Gillies, Cedar Rapids, was recently appointed associate professor of roentgenology at the University of Iowa College of Medicine, Iowa City. —Dr. Erwin Schenck, Des Moines, has been appointed a member of the state board of medical examiners. —Dr. George H. Parmenter has taken over the duties of chief of the medical staff at the U. S. Veterans' Hospital, Des Moines. He held a similar position in Fort Harrison, Mont. —Dr. Hubert L. Hollenbeck, Osceola, is retiring from active practice on account of ill health. Dr. William L. Wall, formerly of Osceola, will take over Dr. Hollenbeck's practice.

Graduate Courses.—Nearly one sixth of the membership of the Iowa State Medical Society is enrolled for the fall series of courses promoted by the speakers' bureau, the journal of the society reports. The medical course is being given in Dubuque, Davenport and Fort Madison, while the one on surgery is in Humboldt, Ames and Ottumwa. Both courses are running for ten weeks. In addition, fifty-two physicians in the northeastern section of the state are taking the short graduate course on anatomy, planned by a specially appointed committee of the First District Medical Society. Dr. Ewen M. MacEwen, professor of anatomy, State University of Iowa College of Medicine, is lecturing in this series, which opened in September and will continue on the second Thursday of each month until April. The lectures are given in the Miller Hotel in New Hampton.

KANSAS

New Editorial Board.—The October issue of *The Journal of the Kansas Medical Society* introduces a new editorial board which, with Dr. William M. Mills, Topeka, as editor, is comprised of Drs. Lucien R. Pyle, Robert B. Stewart and Floyd C. Taggart, Topeka. Clarence Munns is the managing editor. Formerly there were twelve associate editors.

Preventive Medicine Program.—A special meeting was held by the Sedgwick County Medical Society, Wichita, October 9, to consider the subject of preventive medicine. Henry F. Vaughan, Dr. P.H., health commissioner of Detroit, was the principal speaker. With this meeting the committee on public health of the society launched a "sustained project in the field of prevention." Dr. Hugh L. Dwyer reported on immunization campaigns in Kansas City, Mo.

Personal.—Dr. Edwin D. Ebricht, Wichita, was awarded the president's cup on winning the annual golf tournament of the Sedgwick County Medical Society, September 21; his score was 80. A new challenge trophy, presented by Dr. Hal E. Marshall, Wichita, was won by Dr. Norris L. Rainey, Wichita, for low net score. —At a recent meeting of the Brown County Medical Society, Dr. Raymond J. Portman, Hiawatha, was presented with a set of sterling silver as a token of esteem by Dr. William G. Emery on behalf of the society. Dr. Portman has moved from Hiawatha to Antigo, Wis.

MASSACHUSETTS

Society News.—A symposium on pneumonia will be conducted before the Suffolk District Medical Society, November 28, by Drs. Fredrick T. Lord, Edward D. Churchill and Roderick Heffron, Boston. Mr. Sidney Lamb, secretary of the Mersey Hospital Council, Liverpool, England, discussed voluntary health insurance before the society, October 12. —Dr. Arthur P. Noyes, Howard, R. I., addressed the New England Society of Psychiatry in Waltham, October 10. His subject was "Psychotherapy in State Hospitals." —Dr. Frederick A. Collier, professor of surgery, University of Michigan Medical School, Ann Arbor, Mich., discussed "Water Losses in Surgical Patients" before the Harvard Medical Society, October 23. —At a meeting of the William Harvey Society, October 17, Dr. Emil Novak, Baltimore, spoke on "The Endocrines in Gynecology." —Drs. Max Ritvo, Boston, and George A. Moore, Brockton, discussed gastroduodenal hemorrhages from the roentgenologic and surgical points of view, respectively, before the Plymouth District Medical Society at Brockton, October 25. Dr. Alfred L. Duncombe, Brockton, considered the "Treatment of Barbiturate Poisoning."

MINNESOTA

Medical Field Representative.—George B. Larson, St. Paul, has been named to the newly created position of medical field representative for emergency medical relief for the Minnesota State Medical Association. Mr. Larson, who took over his duties September 4, has for the last six years been executive secretary of the Polk County Medical Society, Frederic, Wis. One of his first undertakings will be the organization of emergency advisory and contact committees in each county.

NEBRASKA

Clinical Assembly in Omaha.—The Omaha Midwest Clinical Society will present its second annual assembly, October 29-November 2, with headquarters at the Hotel Paxton. Lectures in general assembly by guest speakers, lecture courses given by Omaha physicians and clinics will make up the week's program. Guest speakers will be the following:

Dr. Walter L. Bierring, Des Moines, Iowa, President of the American Medical Association, The Educational Function of the American Medical Association.

Dr. Richard H. Jaffe, Chicago, The Value of Biopsy; Pathology of Essential Hypertension.

Dr. Carl Henry Davis, Milwaukee, Hypothyroidism in Gynecology and Obstetrics; Indications for Cesarean Section.

Dr. Cyrus C. Sturgis, Ann Arbor, Mich., Treatment of Some Types of Secondary Anemia; Diagnosis and Treatment of Pernicious Anemia.

Dr. Willis C. Campbell, Memphis, Tenn., The Process of Bone Growth and Repair; Arthroplasty.

Dr. John Oliver McKeynolds, Dallas, Texas, What the General Practitioner Should Know About Ophthalmology; Differential Diagnosis of Intra-Ocular Affections and Practical Points in Their Management.

Dr. Alfred I. Folsom, Dallas, Texas, Prosthetic Resection; Bladder Irritation in Women.

Dr. Frank H. Lahey, Boston, Diagnosis and Management of Peptic Ulcer; Carcinoma of the Colon.

Dr. Benjamin H. Orndoff, Chicago, The State of the Breast Before It Becomes Cancerous; Cancer of the Breast and Its Management.

Dr. Foster Kennedy, New York, Acute Head Injuries; Necrosis Following Injury.

Dr. William H. Guy, Pittsburgh, Management of Syphilis in General Practice; Drug Eruptions.

Dr. Albert Graeme Mitchell, Cincinnati, Tonsillectomy—Its Indications; Nephritis and Nephrosis.

NEW JERSEY

Anniversary of Preventorium.—The twenty-fifth anniversary of the establishment of the Tuberculosis Preventorium for Children at Farmingdale was observed at a luncheon, October 6. Speakers included Dr. Herbert R. Edwards, chief of the tuberculosis division of the New York City Department of Health, and Dr. Charles Hendee Smith, New York.

NEW YORK

Society News.—At the annual meeting of the eighth district branch of the Medical Society of the State of New York in Jamestown, October 4, speakers were: Drs. Joseph S. Lawrence, Albany, on "Successful Application of the Welfare Law"; George W. Cottis, Jamestown, "Nondrainage Treatment of Peritonitis"; Wallace B. Hamby, Buffalo, "Development and Present Status of Neurosurgery," and Malcolm H. V. Cameron, Toronto, Ont., "Gallbladder Disease." Dr. Arthur J. Bedell, Albany, president of the state medical society, also made an address.—Dr. Frank M. Dyer, Binghamton, addressed the Broome County Medical Society in Binghamton, October 9, on "The Tragedy of Appendicitis—The Other Side."—Dr. Anthony Bassler, New York, addressed the Dutchess-Putnam Counties Medical Society, Poughkeepsie, October 10, on chronic colitis.—Dr. Jean A. Aubry, Rochester, addressed the Ontario County Medical Society, Geneva, October 9, on "The Puerperium, with Special Reference to Prenatal and Postnatal Care."

New York City

Malnutrition Among School Children Declines.—A recent analysis of results of medical examinations of school children in the first half of 1934 compared with similar figures for previous years shows a distinct decline in malnutrition, the *Quarterly Bulletin* of the New York City Department of Health reports. Despite the fact that no satisfactory standard of measuring malnutrition has been devised, the fact that the examinations were made by practically the same inspectors over a period of years makes it likely that the changes noted are significant, the report says. For the first half of 1934 the percentage of children considered malnourished was 17.7. For 1933 the percentage was 19.9 and for 1932, 21.1. In 1929 the percentage was only 13.4.

Diseases Under Investigation at Rockefeller Institute.—Cases that bear on a limited number of subjects chosen for investigation may be referred to the Hospital of the Rockefeller Institute for Medical Research by physicians who are willing to cooperate, according to an announcement. The following diseases are now under investigation: acute lobar pneumonia and bronchopneumonia in adults; measles in the pre-eruptive stage, chickenpox; encephalitis following measles, vaccinia, chickenpox, whooping cough or common cold; rheumatic fever in any early acute form and sore throat in rheumatic subjects; advanced heart disease, especially in older persons; nephritis in initial acute stages, nephrosis, arteriosclerotic nephritis, essential hypertension; aplastic, idiopathic pernicious or severe microcytic anemia; sprue or severe glossitis and stomatitis without anemia. Physicians should communicate by telephone or by personal application before sending patients. No charge is made for any service.

NORTH CAROLINA

Personal.—Dr. Robert S. McGeachey, Greenville, health officer of Pitt County for four years, has been appointed to a similar position in Halifax County.—Dr. Clarence L. Guyton Jr. has been made head of the Ellen Fitzgerald Hospital, Monroe, succeeding the late Dr. Alto F. Mahoney.—Two new members have been added to the faculty of the University of North Carolina Medical School this year. Dr. Augustus S. Rose, formerly of the faculty of Harvard Medical School, will be associate professor of anatomy, and Dr. Walter Reece Berryhill, formerly of Western Reserve University School of Medicine, associate professor of pathology and physical diagnosis. Dr. Berryhill will also be chief of the medical staff of the university infirmary.

OHIO

Health Service at State University.—Reorganization of the medical and health service at Ohio State University, Columbus, with Dr. John W. Wilce as director, was recently announced. Dr. Wilce will hold the rank of professor of medicine in the medical school. Other members of the staff and their rankings on the medical faculty are Drs. Morse F. Osborn, associate professor; James A. Beer, Shirley Armstrong and Charlotte Winnemore, assistant professors, and James M. Foley, instructor.

Institute for Graduate Instruction.—Through the interest of Toledo alumni of the old Toledo Medical College, which was closed in 1914, it has been decided to use a fund set aside at that time by the retiring board of trustees to establish the Medical Institute of the University of Toledo for graduate medical education. The first annual presentation will be given November 2 at an all day meeting in the Doermann Auditorium, University of Toledo, at which Drs. Lawrason Brown, Saranac Lake, N. Y., and Everts A. Graham, St. Louis, will lecture on medical and surgical aspects, respectively, of diagnosis and treatment of pulmonary tuberculosis. The Toledo Academy of Medicine will meet with the institute for the closing evening lecture.

Personal.—Dr. Carl L. Spohr has been made acting head of the department of pathology, Ohio State University School of Medicine, Columbus, succeeding the late Dr. Ernest Scott.—Dr. John Uri Lloyd, Cincinnati, received the Procter International Award of the Philadelphia College of Pharmacy and Science at a ceremony, October 9, in recognition of contributions to pharmacy. The award, a suitably inscribed gold watch, is named in honor of William Procter Jr. (1817-1874), for many years a member of the faculty of the college.—Dr. T. Addison McCann, Dayton, was guest of honor at a dinner given by physicians of Dayton, September 25, at the Hotel Van Cleve, celebrating his seventy-fifth birthday.—Dr. James J. Marek, Cleveland, won the annual golf tournament of the Ohio State Medical Association in Columbus, October 3, with a score of 157 for thirty-six holes.—Dr. Abram L. Van Horn, Cleveland, has been appointed chief of the bureau of child hygiene of the state department of health, Columbus.

OKLAHOMA

Society News.—Speakers at the quarterly meeting of the Western Oklahoma Medical Society in Clinton, September 16, were Drs. Wallace J. Masters, on preventive pediatrics; Milton H. Glover, diagnosis and treatment of fractures, and Orman T. Kimbrough, urology. All are from Wichita Falls, Texas.—Drs. McClain Rogers and Roger L. Hickman, Clinton, addressed the Woods-Alfalfa Counties Medical Society, Alva, September 25, on disease of the gallbladder and tuberculosis, respectively.—Drs. Alfred L. Seal, Concho, and Myron S. Gregory, Oklahoma City, addressed the quarterly meeting of the Canadian County Medical Society, El Reno, October 6, on undulant fever and on paranoia, respectively.—At a meeting of the Jackson County Medical Society at Altus, June 22, speakers were Drs. William G. Husband, Hollis; Emory S. Crow, Olustee; John M. Allgood and Raymond H. Fox, both of Altus, on various aspects of appendicitis.

PENNSYLVANIA

State Medical Election.—Dr. Alexander H. Colwell, Pittsburgh, was named president-elect of the Medical Society of the State of Pennsylvania at the annual session in Wilkes-Barre, October 3. Vice presidents elected are Drs. Peter P. Mayoek, Wilkes-Barre; William G. Tillman, Easton; Thomas St. Clair, Latrobe, and Ward O. Wilson, Clearfield. Dr. Moses Behrend, Philadelphia, was installed as president and Dr. Walter F. Donaldson, Harrisburg, was elected secretary for the seventeenth year. The 1935 meeting will be held in Harrisburg.

District Meeting.—At the annual meeting of the second councilor district of the Medical Society of the State of Pennsylvania, three physicians who had been in practice for fifty years received testimonials from the state society, Drs. Alice Rogers Easby, Media; Robert G. Gamble, Haverford, and John K. Evans, Malvern. Among speakers at the meeting were Drs. John O. Bower, Philadelphia, on reduction of mortality from appendicitis; James W. McConnell, Philadelphia, on mental hygiene, and Leonard G. Rowntree, Philadelphia, on arthritis and its treatment.

Philadelphia

Weir Mitchell Oration.—Dr. Stephen W. Ranson, professor of neurology, Northwestern University Medical School, Chicago, delivered the S. Weir Mitchell Oration of the College of Physicians of Philadelphia, October 17, on "The Hypothalamus: Its Significance for Visceral Innervation and Emotional Expression."

Personal.—Dr. Moses Behrend, president of the Medical Society of the State of Pennsylvania, was the guest of honor at a dinner given by the staffs of Mount Sinai and Jewish hospitals, at the Locust Club, October 17.—Dr. Charles W. Burr has given a laboratory for biology to the Episcopal School, of which he is an alumnus and a trustee.—Dr. Edward L. Bauer has been appointed physician to Girard College to succeed Dr. Frank L. Greenwalt, who retired after thirty years'.

service.—Dr. Thomas C. Stellwagen Jr., professor of genito-urinary surgery, delivered the introductory lecture at the opening session of Jefferson Medical College, September 24, on "Cooperation and Loyalty."

Pittsburgh

Society News.—Speakers at the monthly meeting of the Allegheny County Medical Society, October 16, were Drs. William A. Bradshaw, on Malta fever; Joseph S. Baird, preventive treatment of measles, and Ellen J. Patterson, foreign bodies in food and air passages. The motion picture showing the work of the American Medical Association at headquarters in Chicago was shown by Dr. Austin A. Hayden, Chicago, secretary of the Board of Trustees.—Dr. George A. Holliday addressed the Pittsburgh Urological Association, October 8, on lymphogranuloma inguinale.

SOUTH DAKOTA

Society News.—Dr. Elexious T. Bell, Minneapolis, addressed the Seventh District Medical Society, Sioux Falls, September 11, on diseases of the kidney.—A symposium on cancer of the breast formed the program of the Black Hills Medical Society recently; speakers included Drs. Charles W. Hargens and Charles F. Morsman, both of Hot Springs.

WASHINGTON

Health Survey in Tacoma.—Carl E. Buck, Dr.P.H., field representative of the American Public Health Association, made a ten day survey of public health facilities in Tacoma in September. The survey was an award by the association to the city for a report made some months ago from which it was decided that Tacoma showed the greatest promise of making use of a survey by an expert in connection with the health contest sponsored by the U. S. Chamber of Commerce.

GENERAL

Changes in Status of Licensure.—At a recent meeting of the California Board of Medical Examiners, the following action was taken:

Dr. Egbert G. Johnson, Los Angeles, placed on probation for three years after a hearing of charges of alleged deceptive advertising.

Dr. Edward S. Moulton, Corning, placed on probation for five years without narcotic privileges based on the record of his conviction of violating the state poison law.

Branch Urologic Society Organized.—The Southeastern Branch Society of the American Urological Association was recently organized with the following officers: Drs. Montague L. Boyd, president; Edgar G. Ballenger, president-elect, and Earl H. Floyd, secretary; all are of Atlanta. Membership in the branch organization is open to physicians living in Alabama, Georgia, Florida, Louisiana, North Carolina, South Carolina and Tennessee. The first meeting will be held in Atlanta, December 7-8.

Automobile Fatalities in Four Weeks.—The bureau of the census, U. S. Department of Commerce, announced that eighty-six large cities in the United States reported 733 deaths from automobile accidents during the four weeks ended September 29, as compared with 708 deaths during the four weeks ended Sept. 30, 1933. Of the total number 536 occurred within corporate limits of cities. For the fifty-two week periods ended Sept. 29, 1934, and Sept. 30, 1933, the totals for all cities were respectively 8,691 and 8,005, which indicate a recent rate of 23.3 per hundred thousand population as against an earlier rate of 21.4.

Association for Cancer Research.—The twenty-eighth meeting of the American Association for Cancer Research will be held November 8 in New York at Memorial Hospital. The program is as follows:

Dr. James Ewing, New York, Fascial Sarcoma; Intermuscular Liposarcoma.

Dr. Leila Charlton Knox, New York, Synovial Sarcoma.

Dr. Alphonse A. Thibaudau, Buffalo, Myxosarcoma.

Dr. George H. Semken, New York, Surgical Treatment of Sarcoma of the Soft Parts.

Dr. Fred W. Stewart, New York, Neurosarcoma.

Dr. Joseph McFarland, Philadelphia, Malignant Myoma.

Dr. Traian Leucutia, Detroit, Radiotherapy of Sarcoma of the Soft Parts.

Dr. George Miller MacKee, New York, Idiopathic Multiple Hemorrhagic Sarcoma (Kaposi).

Dermatology Board Examination Canceled.—The American Board of Dermatology and Syphilology has postponed the meeting which was to have been held in San Antonio, November 13-16, at the time of the meeting of the Southern Medical Association until the Atlantic City session of the American Medical Association in June 1935. The oral examination for applicants in groups A and B will be held June 10 in New York City. The written examination for group B will be held, April

29, 1935, in various cities throughout the county. All applications for this examination should be filed in the office of the secretary before March 10, 1935. Application blanks and booklets of information may be obtained from the secretary, Dr. C. Guy Lane, 416 Marlborough Street, Boston.

Society News.—Dr. Lewis J. Moorman, Oklahoma City, was elected president of the Southern Tuberculosis Conference and Dr. Jesse B. Naive, Knoxville, Tenn., president of the Southern Sanatorium Association, at the annual joint meeting in Knoxville, October 11.—Dr. James C. Braswell, Tulsa, Okla., was elected president of the Aero Medical Association at the annual session in Washington, D. C., September 30. Regional vice presidents elected were Drs. Albert M. Mitchell, Terre Haute, Ind.; Francis C. Hertzog, Long Beach, Calif.; John R. Poppen, U. S. N., on duty at Washington, and Bernard L. Jarman, Washington, examiner for the Bureau of Air Commerce. Dr. David S. Brachman, Detroit, was reelected secretary.—Dr. Peer P. Johnson, Beverly, Mass., was elected president of the New England Surgical Society at the annual meeting in Burlington, Vt., September 29. Other officers elected were Drs. Channing C. Simmons, Boston, vice president, and John M. Birnie, Springfield, secretary, reelected. The 1935 meeting will be held in Manchester, N. H.

The 1934 Christmas Seal.—The National Tuberculosis Association commemorates with this year's Christmas seal the fiftieth anniversary of the building of the cottage that became the nucleus of Trudeau Sanatorium, Saranac Lake, N. Y. In 1882, on the publication of Koch's discovery of the tubercle bacillus, Dr. Trudeau began experimental work to prove Koch's work for himself, making his own apparatus. Dr. Trudeau lived till Nov. 15, 1915. He was the first president of the National Tuberculosis Association, in 1904. On the eighty-sixth anniversary of Dr. Trudeau's birth, October 5, officials of the New York state committee on tuberculosis and public health presented to the sanatorium a picture of the cottage, which is now used as a museum, in a ceremony attended by physicians from all parts of the state.

ALASKA

Dr. Murray Made Medical Director of Indian Service.—Dr. Vance B. Murray, surgeon, U. S. Public Health Service, has been detailed for duty as medical director for the Alaskan Medical Service under the office of Indian affairs, department of the interior. Dr. Murray, a graduate of Columbia University College of Physicians and Surgeons, was commissioned in the service in July, 1916. Recently he has been medical director of district number 2 of the Indian Service in Spokane, Wash.

PHILIPPINE ISLANDS

Society News.—Dr. Jose O. Nolasco presented a paper on "Perineural Injections with Antileprotic Drugs" and Drs. Alejandro Laureola and Casimiro B. Lara reported a case of agranulocytic angina at a meeting of the Culion Medical Society, July 26.—At a meeting of the Manila Medical Society, August 14, a symposium on food poisoning was presented by the following physicians: Drs. Jose Albert, Moises B. Abad, Luis Guerrero and Patricio Ignacio, the clinical point of view; Eugenio Hernando, epidemiology; Jose V. Punsalano, Trinidad P. F. Banuelos and Mariano Basaca, laboratory point of view; Liborio Gomez, Sixto de los Angeles and Pablo Anzuarez, pathology.

CANADA

Society News.—Dr. J. Arthur Jarry, Montreal, was elected president of the Congress of French Speaking Physicians of North America at the recent session in Quebec, and Dr. Amédée Granger, New Orleans, vice president. The next meeting will be in Montreal in 1936.—Dr. Gregoire F. Amyot, Vancouver, addressed the Vancouver Medical Association, Vancouver, B. C., October 2, on "Infection, Its Spread and Control." Dr. Clarence E. Brown will speak, November 6, on "Secretory Disturbances of the Stomach."

Changes in Provincial Hospitals.—Dr. George H. Stevenson, superintendent of the Ontario Hospital, Whitby, Ont., has been appointed superintendent of the Ontario Hospital, London, to succeed the late Dr. Fulton S. Vrooman. Dr. Stevenson will also be professor of psychiatry at the University of Western Ontario School of Medicine. Dr. Donald R. Fletcher, now at the Ontario Hospital, Brockville, succeeds Dr. Stevenson; Dr. Charles S. Tennant, superintendent at the provincial hospital at Woodstock, goes to Brockville; Dr. Daniel O. Lynch, superintendent at Penetanguishene, is transferred to

Woodstock, and Dr. Claude A. McClenahan, who has been acting superintendent at London, becomes superintendent at Penetanguishene.

University News.—Dr. Archibald B. Macallum has resigned after many years' service as dean of the University of Western Ontario Faculty of Medicine, London. Dr. Frederick J. H. Campbell, associate professor of medicine, is acting dean.—Dr. Brandur J. Brandon recently retired as professor of surgery at the University of Manitoba Faculty of Medicine, Winnipeg. He was the guest of honor at a dinner given by the honorary attending staff of the Winnipeg General Hospital, August 30.

LATIN AMERICA

Pan American Congress on Tuberculosis.—The Latin American Union of Tuberculosis Societies has organized the third Pan American Congress of Tuberculosis to be held in Montevideo, Uruguay, December 16-19. Five subjects have been chosen for discussion as follows: economic bases of the fight against tuberculosis in South America; pathogenesis and treatment of tuberculous empyema; medicosurgical collapse therapy of pulmonary tuberculosis; review of therapeutics of tuberculosis in Chile, and radiologic aspects of pulmonary tuberculosis.

Government Services

Testing Cattle for Bang's Disease

The testing of cattle for Bang's disease, or "contagious abortion," has been begun in twenty-two states under a federal emergency appropriation, the U. S. department of agriculture announces. Preliminary work indicates that about 15 per cent of the cattle will react to the agglutination test. Farmers in states cooperating in the campaign may sign agreements for testing in which they agree to market reacting animals for slaughter to maintain sanitary safeguards; to safeguard the herd in purchasing new animals and to retest at intervals. The government will pay indemnities up to \$20 for grade cattle and \$50 for pure bred registered cattle.

Gift for Medical Research

Associates of the late Dr. Edgar Orrin Crossman, medical director of the Veterans' Bureau, have presented a fund of \$900 to the U. S. Public Health Service for study, investigation and research into fundamental problems of disease, it was announced October 2. The gift, which was accepted by the Secretary of the Treasury on behalf of the government, was made as a tribute to Dr. Crossman's work in the care and treatment of former members of the naval and military forces. Dr. Crossman died in 1929.

Report on the Civilian Conservation Corps

President Roosevelt, in acknowledging a recent report from Robert Fechner, director of emergency conservation work, on the present status of the Civilian Conservation Corps, indicated that he will continue this project, in which 1,626 physicians have been engaged. As of September 30, there were in the camps 1,089 physicians who are members of the Medical Reserve Corps of the U. S. Army. In addition, 325 are employed on a full time contract basis; 84 on part time contracts; 37 medical officers of the regular army, and 91 medical officers of the Navy. It is estimated that total annual salaries of these physicians amounts to about \$4,500,000. A total of 780,000 men has been enrolled for various periods, the maximum number at any one time being 390,000. The report states that the health of the men is rigorously guarded and that their physical and mental condition is much improved. A check of 15,000 men picked at random revealed an average gain in weight of seven pounds per man. The men have been paid \$136,000,000, of which \$113,000,000 has been sent to their families. Men are now leaving the corps at a rate of about 10,000 per month, the report stated, to accept private employment or for other reasons. At the beginning of the fourth six months' period, October 1, the War Department was to enroll 100,000 additional men to fill vacancies caused by discharges during the previous six months. Officials of the forest service of the department of agriculture report that forestry programs have been advanced from five to fifteen years by the work of the conservation corps, which includes forest fire protection, preservation of forest covers on watersheds, protection against plant diseases, prevention of soil erosion, flood control and improvement of national parks.

A Test of a Vegetarian Diet

The efficiency and performance of a cyclist on a vegetarian diet have been tested at the Institute of Physiology, Glasgow University, in order to see how the strict omission of animal food affected the result. It is well known that athletes who specialize in contests demanding great endurance lay stress on an ample supply of protein in the diet. The persons who call themselves vegetarians usually take milk, eggs and cheese to secure this supply. In the present tests the subject was a man of 48 who had lived on a vegetarian diet for twenty-three years. For many years he had secured numerous prizes and records and was one of the British competitors at the Stockholm Olympics in 1912 and at Antwerp in 1920. He was put on a strictly rationed diet, which was varied in the course of the experiments as regards the source and amount of protein. He pedaled a stationary bicycle almost continuously for more than eight hours daily and each dietary experiment lasted a week. The work done was measured by special devices and an electrical break maintained the sort of resistance that would be experienced on a good level road. The speed was checked at frequent intervals during the tests, and determinations of the metabolism were made.

Four standard diets were employed, in which the protein varied from 39 to more than 200 Gm. derived from strictly vegetable sources. Actually the attempt to secure a really high protein diet from such sources was a failure, owing to the digestive troubles provoked, and this experiment showed the poorest performance of all. A fifth experiment was carried out with no restrictions and the subject chose the sort of food he would take in road racing. This included 5 pints of milk, eight eggs and 1 ounce of butter, in addition to strictly vegetable foods. This diet gave the best athletic performance of the series, with the highest speed records, although the "gross efficiency" (energy produced per unit of food energy) was less. The conclusion is that in prolonged hard muscular exercise the large supply of energy required can best be obtained in small bulk and in palatable form from protein-rich foods of animal origin.

Mental Health Services

In their report for 1933 the Board of Control (the official body which controls the mental health administration) states that satisfactory progress has been made in the development of the mental health service in spite of financial restrictions. The important advance of recent years is the development of voluntary treatment, in contrast to the previous certification and incarceration. The number of voluntary admissions to public mental hospitals shows a steady increase. There has also been a gratifying increase in the number of outpatient clinics, from which an improved voluntary admission rate may be expected. The board is convinced that outpatient work in cooperation with the local physicians is not only the surest way to encourage early inpatient treatment where it is needed but saves many from needing inpatient treatment at all.

During the year the number of persons suffering from mental disorder—voluntary, temporary and certified—in England and Wales was 150,266, an increase of 1,491 over the previous year. The average annual increase for the five years ended 1933 was 1,636. This increase has no necessary connection with the incidence of mental disorders in the general population. Other points brought out in the report are the importance of early treatment, the unhygienic practice still in vogue in certain hos-

pitals of allowing male patients to wear the same underclothing day and night, the suggestion that an interchange of troublesome patients between neighboring hospitals might often be in the interest of the patient and the hospital, and the desirability of the avoidance of printed forms in the replies sent by the authorities of the hospitals to inquiries from relatives. The total number of mentally defective patients in England and Wales in institutions and under guardianship at the end of 1933 was 38,843; in addition there were 31,921 under statutory supervision. The great value of scouting and guiding in the training of mental defectives is emphasized and tribute is paid to the authorities responsible for the control of this movement for their help in devising special tests suitable for mental defectives. The board observes that, apart from their recreational and disciplinary value, scouting and guiding help to vary the monotony of institutional life, while at the same time they increase self confidence and self respect and foster the sense of independence, which is so sadly lacking in most defectives.

Voluntary and Municipal Hospitals

As pointed out previously, the rise of the municipal hospital (supported by taxes) is a phenomenon of recent years. This has not been accompanied by any decline in the hospitals supported by voluntary contributions, which have long been a feature of English life. At the fourth annual conference of the British Hospitals Contributory Schemes Association, held at Bristol, a discussion took place on the relation of voluntary to municipal hospitals. Formerly the voluntary hospitals were purely charitable institutions, supported by philanthropic persons for the benefit of the poor. But the great financial changes of recent years, in the form of increased cost and diminished resources of those who used to give, have rendered charitable support inadequate. Resort has had to be made to provident schemes. These have been successful and there are now about four million contributors. Sir Arthur J. Atkinson, chairman of the Hull Voluntary Hospitals Council, read a paper in which he stated that a financial expert had told him that it would pay a public authority to subscribe to almost any extent to the support of a voluntary hospital to prevent its extinction, for this would mean a great increase of the taxes. But there was a not unimportant school of political thought which aimed at a state-regulated hospital service for all maintained entirely by taxation. If the voluntary hospitals met what was called "their inevitable fate," with their extinction would also disappear the contributory scheme movement and that amazing support which they had always received in the British Isles and which in 1932 amounted to \$76,000,000. In the discussion it was pointed out that local authorities had to build hospitals because of the gaps that existed. An adequate hospital service within reasonable distance of the homes of the people was necessary. Dr. Peter Macdonald, representing the British Medical Association, referred to the promotion of a scheme by his association to do for middle class people what the contributory schemes were doing for the working class. He was enthusiastically in favor of voluntary hospitals and did not think that, with certain exceptions, the municipal hospitals were as efficient.

The Evils of a Smoky Atmosphere

In his presidential address to the National Smoke Abatement Society, Dr. H. A. des Voeux asked whether the great increase that has recently been observed in the cases of cancer of the lung could be attributed to a smoke-laden atmosphere. It was known that tar, which is derived from coal, could produce cancer, and the substance that was responsible had been isolated by the chemists. According to evidence from Glasgow and Manchester, supported by the reports of nearly every health officer, fogs were prolific causes of bronchitis and con-

sequent heart disease, which caused 37 per cent of the deaths in this country. Darkness from the blotting out of sunlight by smoke was one of the chief causes of rickets, which crippled children. In these conditions also lay the ancillary cause of tuberculosis, which was almost impossible to cure without the assistance of clean air and sunshine. Dr. des Voeux commented on the futility of sanatorium treatment. He also spoke of the waste of fuel—the throwing into the atmosphere daily of tar, sulphur and oil to destroy buildings, clothes, books and furniture.

Dr. J. S. Owens, superintendent of observations for the Committee for the Investigation of Atmospheric Pollution, Department of Scientific and Industrial Research, read a paper on "The Measurement of Atmospheric Pollution." He said that ninety-six stations in Great Britain, where atmospheric pollution was measured, recorded an average fall of solid matter of 250 tons a square mile in 1933 and 240 tons in 1934. Mr. O. Cochran, secretary of the Scottish Flying Club, in a joint paper with Mr. W. J. Grassie, meteorological officer, Paisley, said that smoke was carried long distances in quantities sufficient to affect visibility. On many occasions, flying at Renfrew had been brought to a standstill by the smoke haze drifting from Glasgow. R. B. Smith, acting president of the Scottish Branch of the National Smoke Abatement Society, stated that in the United Kingdom nearly 250,000 tons of soot escaped into and polluted the atmosphere every year from domestic fireplaces alone. The only way to stop smoke was to stop the burning of raw coal and provide a better and cheaper means of heating.

Dr. J. J. Jervis, health officer of Leeds, said that the slum and the smoky coal fire were relics of a bygone and visionless age. England owed its reputation for rickety children more to lack of light than to anything else. The soot and grit in the atmosphere inactivated the ultraviolet rays. A feature of slum dwellings that transcended all others was the prodigal way in which coal was used. Dr. Jervis pleaded for the abolition of the smoky coal fire.

Another Death Due to Cinchophen

Cinchophen has been extensively advertised and sold in this country, under the trade name of "Atophan," as a remedy for gout and rheumatism. For some years the liability to the production of toxic jaundice, sometimes fatal, has been noticed. The intermittent administration of the drug, to avoid dangerous accumulation, is recommended. But it has been shown that, even when this method has been followed and only small quantities taken, fatalities still occur. However, this dangerous drug is still used and deaths continue to be recorded. The latest was the subject of an inquest at Birmingham. An electrician, aged 31, was prescribed Atophan for sciatica and gout. Jaundice developed and he died. "The necropsy showed acute yellow atrophy of the liver. His physician said that he had never known ill effects from the use of the drug. Dr. K. Douglas Wilkinson, professor of pharmacology, Birmingham University, gave evidence. He used the drug fairly frequently, but with considerable caution. There had been more than fifty recorded deaths, but there must have been more cases. He considered that the drug should be scheduled as a poison. The coroner said that a warning ought to be issued and that the drug should not be used under any circumstances except under the direct supervision of a physician. At present any one could obtain as much as he wanted from pharmacists.

A National Scheme of Dental Aid

A conference of representatives of charitable institutions interested in the provision of dental treatment has been held in London. It was decided to formulate a scheme for coordinating efforts in providing dental aid to poorer people, estimated

to number 6,000,000, at present not under the National Health Insurance Acts. The conference was convened by the Ivory Cross National Dental Aid Fund. Its object is to unite in a single cooperating body all the dental aid societies, with the object of raising a national fund which will place dental treatment at the disposal of the poor throughout England. Secondly, it is proposed to initiate a campaign of instruction and education in order to teach what the middle and upper classes realize—that care of the teeth is of the first importance in the preservation of health. Bad teeth are stated to be a menace to health, longevity and digestion, as they are a primary channel for many diseases. The report of the school medical officer for London shows a definite falling off in the number of children given dental treatment in the elementary schools. This is due not to any failure on the part of the dentist or the public authorities but to apathy of the parents. Turning to the financial aspect of the question, the sum available per head for dental treatment among the 15 million insured workers is only 66 cents, which is one fourth of the expenditure on medical treatment and about half the annual cost of drugs and bottles. Yet people with an income of \$2,500 and upward spend, on the average, three times as much on the care of their teeth as on medical care.

Recent Complaints About the Quality of Bread

For years, controversies have developed among the agriculturists, the millers, the bakers and the physicians over the quality of bread. Learning all the manipulations to which bread is subjected, the public loses its appetite for bread, which aggravates the agricultural crisis. The main trouble is that the farmer produces too much wheat of mediocre quality. The farmers everywhere have sown wheat of an inferior species, which yields a large number of grains but which contains a low percentage of gluten and does not make good bread. Hence, some hard wheat rich in gluten, such as Manitoba wheat, must be imported and added to it. The demand for this inferior wheat is small. A law requires the miller to pay for the wheat the code price of 115 francs per hundredweight, whereas in foreign countries the price is about 55 francs. To maintain this artificial price, a prohibitive duty has been placed on imported wheat. But no one buys this wheat at the code price. The miller gets around the law by receiving as a present a certain number of supplementary sacks of wheat not mentioned in his bill. But, since the miller was able to produce only inferior flour with this wheat, he has sought to improve it artificially, and a large number of chemical products are sold for that purpose. The flour is whitened with chlorine products and benzoyl peroxide. But the ferments are thereby destroyed and the live yeasts can no longer raise the dough properly. They are therefore replaced by "chemical yeasts" with a base of ammonium persulphate, potassium bromate and magnesium carbonate, and chemical glutens with a base of ammonium persulphate and ammonium phosphate have been introduced. Dough thus prepared rises more rapidly and allows the addition of a larger quantity of water, thus reducing the amount of flour required. This constitutes a great saving for the miller and the baker but brings no profit to the agriculturist whose protection was sought. Such bread is doughy when fresh, and when it gets old it is as hard as cement. The rural population, in the habit of providing a supply of bread sufficient to last several days, refuses to accept it and hence eats more meat and drinks more alcoholic beverages. This poor bread has caused the number of persons with dyspepsia to increase throughout France. The French have always been a people that consumed much bread, and French bread used to be regarded as the best in the world.

The Academy of Medicine is aroused over the matter. It has condemned, in a sharp note, the use of all these ingredients, and demands a return to the normal bread, rich in gluten. The minister dominated by politics, and desirous, above all, of protecting the agriculturists, who constitute a large body of voters, responded in such a manner as to aggravate the situation. He modified the official regulations in regard to bolting so that only 70 per cent instead of 75 per cent of the wheat grain can be utilized for flour, which makes it necessary to employ more wheat for the same quantity of bread but diminishes, at the same time, the quantity of gluten in the flour, a larger part of the gluten than before remaining in the bran. The animals that eat the bran gain more therefore, from the standpoint of health, than does man. In addition, the minister has prohibited the introduction of a small quantity of bean flour that has commonly been added to wheat flour, which increased somewhat the gluten content of bread and kept it fresh longer. The addition of bean flour was the only form of adulteration that was unobjectionable. The agriculturists are so powerful politically that they have brought about also a limitation of the importation of rice into France under the pretext that it might compete with wheat, and already grave difficulties have arisen with the French colonies of the Far East, which depend chiefly on the cultivation of rice for their living.

Mitogenetic Radiations

Mitogenetic radiations were the subject of a recent research by Marinesco, Jonesco-Sisesti and Sager, the results of which they presented to the Academy of Medicine. It is alleged that all living beings, both animal and vegetable, emit radiations that will leave an impression on a photographic plate wrapped in black paper, as was demonstrated some time ago by Commandant Darget, and this radiation, which varies with the individual, can be measured as one measures radioactivity by ionization of the air between two armatures in the conductors of which an electric current is induced. Gourvitch proved the existence of a transmission, through the roots of vegetables, of an ultraviolet radiation that promoted multiplication of cells. That is what is called mitogenetic radiations. Marinesco and his collaborators measured the mitogenetic radiations of the blood by two different methods, which gave similar results. It appears that this radioactive potency varies in normal subjects with the age, being at its maximum in the child and diminishing steadily, becoming almost nil in aged persons. It also varies greatly with various types of disease, increasing in some and diminishing in others. Marinesco noted that in a divided nerve the central end is more radioactive than the peripheral end, which he explains by saying that the oxidizing process is more marked in the central end owing to a special influx from the nerve centers. It has been found that this power is increased in the rabbit by intense illumination of the fundus of the eye. These experiments will be continued.

Professor Léon Bernard

The death of Prof. Léon Bernard, at the age of 62, from a septicemia resulting from the opening of a simple dental abscess, is announced. Professor Bernard held a high place in French medicine owing to the stimulus that he had given to the organization of the crusade against tuberculosis. His career had been brilliant. While associate professor at the Faculté de médecine and physician to the "hôpitaux de Paris," he became the first appointee to a special chair for the study of tuberculosis. In the Hôpital Laennec he had organized the Léon Bourgeois dispensary for the detection of tuberculous persons. He was vice president of the Conseil consultatif d'hygiène de France. He was also the permanent representative of France to the health commission of the League of Nations. To the tribune of the Academy of Medicine he presented numerous communications.

Is There a Filtrable Tuberculosis Virus?

A convention on tuberculosis was recently held in Pistoia in Tuscany. Silvestrini, medical clinician of Perugia, in discussing certain forms of the virus, said that it may assume an actinomycotic, a streptococcic, a coccic or a bacillary form. The existence of a granular form, beyond the limits of visibility, cannot be excluded. Depending on the form it assumes, the tuberculous virus provokes diverse reactions in the tissues. Against the denial of the existence of filtrable portions in materials containing tuberculous virus, it is an established fact that something passes into the filtrates which is capable of producing in guinea-pigs a disease that is not typical tuberculosis but tuberculous disease without tubercle bacilli. This condition can be attributed to non-acid-resistant, non-gram-resistant filtrate particles that lie beyond the limit of visibility. These particles may reproduce themselves for a time in the ultravisible form, but, as they originated from bacilli and acid-resistant granules, they may return to these forms. To admit the existence of this filtrable virus is in harmony with the accepted views of the morphology of *Mycobacterium tuberculosis* and, on the other hand, takes account of observed facts in the field of pathology.

Petragnani, director of the Hygienic Institute of the University of Siena, spoke on methods for studying the tuberculous virus. After many years of research, he was inclined to speak conservatively. It is not known what is the true clinical and pathologic picture caused by the ultravirus, although death from cachexia and polyadenia may be an occasional observation. The results obtained by various investigators are not constant and are often contradictory. The existence of a filtrable type of virus has been, in recent years, denied by an ever increasing number of investigators.

Salvioli, director of the Pediatric Clinic in Siena, reported on his studies on the Petragnani anatuberculin in vaccinations on children. In the goutte de lait at Siena the mortality in the annexes, during the four years preceding 1933, was 33 per cent; in 1933, after the application of antituberculosis vaccination, the mortality was 14 per cent.

Fiore, director of the Pediatric Clinic in Pisa, affirmed that today tuberculous infection is not conceived as due solely to Koch's bacillus but as due to a complex virus, which, beginning with the granular and bacillary forms with varying cultural and pathogenic behavior, develops into the ordinary Koch bacillus. The tuberculous protogens show a marked affinity for the lymphatic system, provoke a disease susceptible of cure, do not necessarily elicit sensitiveness to tuberculin, and may develop an immunizing capacity toward the action of the Koch bacillus. To the infection resulting from tuberculous protogens may be assigned the term "pretuberculosis," but designating, according to the speaker, a well defined clinical entity; namely, the complex of all those manifestations that are evidenced in children through the direct action of the protogens. The speaker is convinced that immunity originates from pretuberculosis.

Raspi, of the Pediatric Clinic in Pisa, considered the possibility of increasing the virulence of the tuberculous ultravirus, by employing filtrates of twenty-day cultures in a Besredka fluid culture medium. If suspensions of inert substances capable of irritating the serosa and of provoking an active leukocytic exudation are previously injected into the peritoneum, the successive inoculation into the peritoneum of the filtrate causes in a more evident manner than in the controls the development of a morbid type characterized by glandular hyperplasia with a very rapid course. Raspi provoked a typical tuberculous

infection in guinea-pigs; then, by injecting the filtrate of the spleen and the lymph glands of such tuberculous guinea-pigs into other guinea-pigs he secured the experimental syndrome of the ultravirus. The fourth passage of glandular fluid into a tuberculous guinea-pig caused the rapid evolution of a typical Koch phenomenon.

As a result of successive experiments, the speakers are of the opinion that, in addition to the ultravirus, there are non-filtrable protogens in the cerebrospinal fluid of meningitis patients, which are capable of provoking the well known morbid picture due to the filtrable virus.

Gentili discussed the value of allergy in the diagnosis of tuberculous infections in children. Admitting that clinical manifestations of the ultravirus itself and of tuberculous protogens in a wider sense may be observed, he concluded that the tuberculin tests are losing ground as a diagnostic method.

The Crusade Against Malaria

The government recently experimented in the village of Ardea, in connection with the crusade against malaria. The village of Ardea was selected because it presented various features useful for the test: a small population (700 inhabitants), which was easily supervised; an abundance of stagnant water; houses without protecting screens; the collection of houses (*caseggiato*) located on a hill and hence isolated. The experiment was begun in May 1932. The choice of this village was based on the observation that pigpens attract, more than do the homes, the *Anopheles* mosquito. The area chosen for the experiment was bounded by an imaginary peripheral line connecting twenty-seven pigpens. In 1933, 628 *Anopheles* mosquitoes were caught in the dwellings, 24,961 in pigpens, and 1,068 in the stables of other animals. It is evident, therefore, that the mosquitoes preferred the blood of barrows to that of man.

In 1932 there were sixty-three malaria patients among the population, all of whom, with the exception of one, had a recurrence of the disease. In 1933, there were only forty-nine recurrent cases, and no new cases. None of the persons born during these two years had contracted malaria. The use of quinine had diminished, and the antimalaria prophylaxis station located in that area could be abolished.

Professor Ottolenghi

An acute disease that arose on the last day of his course of lectures caused the death of Prof. Salvatore Ottolenghi, director of the Institute of Legal Medicine of the University of Rome and of the Scuola superiore di polizia scientifica. Born at Asti in 1861 and graduated at Turin in 1884, Ottolenghi obtained, in 1893, by competitive examination, the chair of legal medicine at Siena. In 1896, he organized a university course in "polizia scientifica," which led to the foundation of the Scuola superiore di polizia scientifica. In 1903, he was transferred to the University of Rome. To Ottolenghi belongs the merit of having applied to police administration the technical methods introduced by Bertillon, Galton and Gross, and, further, of having introduced the experimental scientific method into all the functions of police administration. The method, based essentially on the criteria of psychologic anthropology, was used in connection with identification, in the study of clues obtained at the scene of a crime, in the securing of information and of testimony, in the questioning of persons suspected of crime, and, above all, in the practical objective study of the delinquent (biographic files) for the purpose of ascertaining how dangerous to society a delinquent may be, which is the basis of all measures of prevention. He published numerous treatises, the best known of which are that on forensic psychopathology (in collaboration with De Sanctis) and that on "Scientific Police Administration."

JAPAN

(From Our Regular Correspondent)

Sept. 21, 1934.

The Birth Rate and the Infant Mortality Rate

The statistical bureau of the cabinet has issued a report on births, deaths and marriages: The birth rate has shown a tendency to decrease in the last decade, although the population has been increasing. The recent large increase in population may be due to the decline in mortality.

Table 1, giving the number of births per thousand women in the child-bearing age, shows the decline of the birth rate.

TABLE 1.—*Births per Thousand Women in the Child-Bearing Age*

Year	From 15 to 45		From 20 to 29	
	Number	Index	Number	Index
1920.....	171	100	486	100
1925....	166	97	451	93
1930..	155	91	415	85

The following considerations throw light on whether the decline of the birth rate is due to the advance of the average age of married women or to the decrease of the number of births: More than 500,000 women married annually during the years from 1921 to 1927 and since then the number of marriages has been in the neighborhood of 400,000 annually. The decrease in marriages in spite of the great increase in the number of marriageable women since 1927 is due to the advance in age of those who marry, as is illustrated in table 2, giving the rate of married women per thousand women in the child-bearing age.

TABLE 2.—*Marriages per Thousand Women in the Child-Bearing Age*

Year	15 19	20 24	25-29	30 34	35-39	40 44
1920	166	649	857	894	881	846
1925	132	671	876	904	889	849
1930	110	637	886	914	916	864

The decline of the marriage rate of women in the age most favorable for child bearing causes the general decline in the birth rate. The decline in the number of marriages is due to unemployment, with a consequent difficulty in earning a livelihood. Infant mortality is also declining, as is shown in table 3.

TABLE 3.—*Infant Mortality*

Year	Mortality per 1,000 Births
1921.....	164
1922	166
1923	163
1924	156
1925	142
1926	137
1927	142
1928	138
1929	142
1930	124
1931	132

Early American Influence in Japan

The Japanese are aware, writes Dr. F. Shiga in a newspaper, that for the progress and prosperity of their empire they owe a great deal to their American friends. This is why they manifested such enthusiasm at the "Black Ship Festival" at Shimoda in celebration of the eightieth anniversary of the first American-Japanese treaty. The surprise visit of Commodore Perry in 1853 to appeal to the shogunate for com-

mercial intercourse between the two countries aroused the nation. His ship, being the first steamship that the Japanese ever saw, was then called "the black ship" on account of its color. It is not entirely out of place here to recall some of those American friends whose services have caused them to be enshrined in the hearts of the Japanese people.

In the realms of political economy, diplomacy, jurisprudence and postal service there were numerous benefactors. Although less widely known, the medical personages who came to this country from America cannot be forgotten. Dr. John Berry of Massachusetts came to Japan in May 1872 and established a public hospital at Okayama. He devoted himself later to improving health conditions in Japanese prisons. Dr. B. Simons came over in 1859 and opened a public hospital at Yokohama. He was a benefactor of Japanese children suffering from roundworm and came to be known as "Master Santonin" among Japanese parents. To Miss Richard, a Christian missionary, Japan owes the present development of hospital nurse training. Japan had no hospital nurses until Miss Richard arrived in 1883. She applied to the Japanese government on arrival with the support of the American Evangelical Association, for the initiation of a hospital nurse training service. Her movement was successful and in 1886 the first training school of Christian hospital nurses was established. This led to the creation of St. Luke's Hospital, and the nurses annually turned out by the school contributed to the present development of the Red Cross and Charity Hospital here. Mr. William Eliot Griffiths came here in 1870 and was employed as a teacher of the clansmen's children in Fukui province. Two years later he came to Tokyo as a university professor, and during his professorship he separated chemistry from pathology and made it an independent science in this country. Mr. Edward S. Maudslayi came over in 1877. He stayed only two years as professor of zoology and biology, but his contribution to scientific study in Japan was remarkable. He introduced Darwinism to Japan. He discovered the famous shell mound in Omori. He also established a course in anthropology in the Tokyo Imperial University. The list might be extended, but that given is sufficient to afford some idea of the part which American friends contributed to our development, and for which the Japanese nation will forever be grateful.

The Life Insurance Companies and Physicians

The life insurance companies are reported to have an intention to stop entrusting practitioners with physical examination of the persons to be insured. They expect to insure people without the usual physical examination. They intend to have instead an observer who will accompany the clerk and the insured, and estimate his health in a different way from that of the physician, inspecting only his outward appearance. For several years a certain company has been trying this new way with satisfactory results. They employed as observers the retired hospital sergeant majors of the army, who are so well accustomed to judging health. They are said to be able to discern intuitively even the extent, degree or nature of sickness through their many years of experience, never making a mistake. If this plan is successful, nothing would be more convenient for the companies. The military authorities have long been troubled about what to do with these sergeants when they are retired. Of course these observers will serve for ordinary occasions, but if a special examination is required a licensed physician will be sent for. The only question left unsettled is whether these observers should be permitted from the standpoint of insurance and medical regulations. The companies are at present believed ready to go so far as to revise their contract regulations with the sanction of the government. If this becomes general it will be a heavy blow to the practitioners, who already face many economic difficulties.

Marriages

RAY McARTHUR FREEMAN, Ogdensburg, N. Y., to Miss Verna Mae Lamphear of New York, October 6.

ASHBY STEELE, Jefferson Barracks, Mo., to Miss Myrne Moffit of Cedar Rapids, Iowa, September 8.

FREDERICK D. STUBBS, Wilmington, Del., to Miss Marion Virginia Turner of Philadelphia, June 2.

THOMAS JOSEPH CONLEY JR., Chicago, to Miss Elizabeth M. Cardwell of Evanston, October 10.

MIDDLETON ELLIOTT RANDOLPH to Miss Agnes Pickett Davis, both of Baltimore, October 6.

CHARLES LINCOLN STODDARD to Mrs. Nora C. Baehrig, both of San Diego, Calif., recently.

NED C. WATTS, Taylorsville, N. C., to Miss Gladys Ausmus of La Follette, Tenn., October 9.

MATTHEW JEROME MCNEELY to Miss Virginia McLeod, both of Berry, Ky., July 20.

JOHN W. STICKNEY to Mrs. Mabel C. Jennings, both of New York, September 1.

STEPHEN T. TURNER, Barberton, Ohio, to Miss Olga Zachar, September 15.

Deaths

Louis Gaston Labat ☉ New York; Université de Paris Faculté de médecine, 1920; clinical professor of surgery, New York University, University and Bellevue Hospital Medical College; member of the Associated Anesthetists of the United States and Canada; on the staffs of the Woman's, New York Orthopedic, Mount Sinai and Presbyterian hospitals; aged 56; died, October 1, at his summer home at Lake Mohegan, N. Y., of myocarditis.

Paul Galpin Shipley, Baltimore; Yale University School of Medicine, New Haven, 1913; associate professor of pediatrics, Johns Hopkins University School of Medicine; member of the American Pediatric Society and the American Society for Clinical Investigation; fellow of the American College of Physicians; on the staff of the Johns Hopkins Hospital; aged 46; died suddenly, September 12, of heart disease.

Edward Frank Ziegelman ☉ San Francisco; Jefferson Medical College of Philadelphia, 1912; member of the American Academy of Ophthalmology and Oto-Laryngology, American Laryngological, Rhinological and Otolological Society and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; aged 50; died on the train, October 12, of angina pectoris.

Ernest Elmo Archer, Paintsville, Ky.; University of Louisville School of Medicine, 1910; member of the Kentucky State Medical Association; formerly mayor of Paintsville; served during the World War; aged 45; medical director and superintendent of the Paintsville Hospital, where he died, September 20, of heart disease.

Eugene P. King, Providence, R. I.; Jefferson Medical College of Philadelphia, 1880; member of the Rhode Island Medical Society; for many years second deputy superintendent and second deputy city registrar; aged 79; died, September 6, in the Jane Brown Memorial Hospital, following an operation for intestinal obstruction.

Alexander Nelson Booth, Bentleyville, Pa.; Jefferson Medical College of Philadelphia, 1887; member of the Medical Society of the State of Pennsylvania; past president of the Washington County Medical Society; for many years member of the board of education; aged 70; died suddenly, September 28, of heart disease.

Allen Donald McLean ☉ Medical Director, Captain, U. S. Navy, retired, San Diego, Calif.; Detroit College of Medicine, 1895; fellow of the American College of Surgeons; entered the Navy in 1903 and retired in 1928 for incapacity resulting from an incident of service; aged 60; died, September 29, of bronchiectasis.

Boyd Cline Bly ☉ Bryan, Ohio; Ohio State University College of Medicine, Columbus, 1925; past president and secretary of the Williams County Medical Society; aged 39; died, September 13, in a hospital, at Garrett, Ind., of heart disease, pulmonary abscess and acute nephritis.

William Alexander Clark, Trenton, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1879; served

during the World War; on the staff of the Mercer Hospital; aged 77; died, October 2, of chronic myocarditis and occlusion of the coronary artery.

Homer Genung ☉ Freeville, N. Y.; Homeopathic Hospital College, Cleveland, 1884; since 1921 health officer of Dryden and Freeville; on the staff of the Tompkins County Tuberculosis Hospital, Trumansburg; aged 76; died, August 7, of coronary occlusion.

Henry Howitt, Guelph, Ont., Canada; Faculty of Medicine, Trinity College, Toronto, 1873; M.R.C.S., England, 1879; fellow of the American College of Surgeons; on the staffs of the Guelph General Hospital and St. Joseph's Hospital; aged 85; died, July 22.

Robert Bruce Stephenson, Libertyville, Iowa; Starling Medical College, Columbus, 1885; aged 77; died, September 15, in the Jefferson County Hospital, Fairfield, of injuries received when he fell from the porch while cutting a branch of a tree.

Lawrence Waldo Pence, Milwaukee; State University of Iowa College of Medicine, Iowa City, 1898; served during the World War; on the staff of the Veterans' Administration Facility; aged 59; died, September 21, of heart disease.

Robert Dennis Williams, Marked Tree, Ark.; Memphis (Tenn.) Hospital Medical College, 1898; formerly sheriff of Senatobia, Miss.; aged 67; died, August 5, in the Baptist Hospital, Memphis, Tenn., following a gallbladder operation.

Cecil Clair Davis, Albuquerque, N. M.; George Washington University School of Medicine, Washington, D. C., 1918; member of the New Mexico Medical Society; aged 43; died, July 31, of hypertension, myocarditis and uremia.

George Bonnie Wheeler, Lexington, Ky.; College of Physicians and Surgeons, Baltimore, 1912; aged 50; died, September 12, in a hospital at Charleston, W. Va., following an operation for cirrhosis of the liver with ascites.

William G. Kiger, Brunswick, Miss.; University of Louisiana Medical Department, New Orleans, 1876; member of the Mississippi State Medical Association; formerly member of the state legislature; aged 87; died, July 19.

Chauncey Fairfield Brown, Hengchow, Hunan, China; Cornell University Medical College, New York, 1920; medical missionary; aged 45; died, September 24, following an operation for partially strangulated inguinal hernia.

Ambrose C. Herman, Lansdale, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1881; member of the Medical Society of the State of Pennsylvania; aged 76; died, August 31, of carcinoma of the rectum.

Charles Foster Campbell, Sunbury, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1893; formerly on the staff of the Mary M. Packer Hospital; aged 66; died, September 10, of myocarditis and spondylitis.

Edward Worthington Connolly, Vancouver, B. C., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1900; M.R.C.S., England, 1913, and L.R.C.P., London, 1913; aged 60; died, August 30, of heart disease.

Frank Edwin Wolfe ☉ New Albany, Ind.; Kentucky School of Medicine, Louisville, 1897; on the staff of St. Edward's Hospital; aged 58; died, September 21, of arteriosclerosis, coronary occlusion and uremia.

William Miley Rivers, Yemassee, S. C.; University of Oklahoma School of Medicine, Oklahoma City, 1915; member of the South Carolina Medical Association; served during the World War; aged 43; died, July 20.

Ramon Ruiz-Arnau, San Juan, P. R.; Universidad Central de España Facultad de Medicina, Madrid, Spain, 1897; member of the Medical Society of the State of New York; aged 60; died, June 1, of angina pectoris.

John Henry Gosnell, Manchester, Wash.; University of Oregon Medical School, Portland, 1920; aged 42; died, September 14, in the Virginia Mason Hospital, Seattle, of diverticulitis with perforation and peritonitis.

Phillip Leslie McClure, Paris, Ky.; Louisville (Ky.) Medical College, 1891; member of the Kentucky State Medical Association; aged 64; died, August 30, in the W. W. Massie Memorial Hospital, of heart disease.

James Hudson Smart, Dallas, Texas; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; formerly city health officer; aged 66; died, September 17, of angina pectoris.

William Landis Heilman, Sterling, Neb.; Ensworth Medical College, St. Joseph, Mo., 1897; member of the Nebraska State Medical Association; formerly a pharmacist; aged 79; died, July 16, of heat stroke.

Willard Carl Barnes Feld, St Louis; University of Pennsylvania School of Medicine, Philadelphia, 1892, aged 73, died, August 30, in the City Hospital, of a skull fracture sustained when struck by a street car.

John James Dever, Glens Falls, N. Y., Albany (N. Y.) Medical College, 1896; for twenty years county coroner, on the staff of the Glens Falls Hospital, aged 63; died, September 21, of chronic nephritis.

William Tally Baines, Blountsville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1888, aged 73, died, September 24, in St Vincent's Hospital, Birmingham, of carcinoma of the prostate.

Harry Dudley Bell, Oakland, Calif., Cooper Medical College, San Francisco, 1904, aged 55, died, August 4, in the Peralta Hospital, of myocarditis, coronary occlusion and operation for hyperthyroidism.

Hall M. Eddleman, Gastonia, N. C., College of Physicians and Surgeons, Baltimore, 1886, member of the Medical Society of the State of North Carolina, aged 76, died, September 23, of nephritis.

Frank John Novak Sr., Chicago, Rush Medical College, Chicago, 1885, on the staff of the Frances E. Willard Hospital, aged 70; died, October 3, at his home in Riverside, Ill., of coronary thrombosis.

Willard Bryant Carpenter, Columbus, Ohio, Hahnemann Medical College of Philadelphia, 1879, aged 78, died, September 19, in the Grant Hospital, of diabetes mellitus and hypertrophy of the prostate.

William George Kleinstuber, Graterford, Pa., Jefferson Medical College of Philadelphia, 1893, aged 63, died, August 15, in the Temple University Hospital, Philadelphia, of peptic ulcer and myocarditis.

Julius B. H. Day, Social Circle, Ga., University of Louisville (Ky.) School of Medicine, 1891, member of the Medical Association of Georgia, aged 66, died, September 7, of carcinoma of the colon.

William Herbert Riley, Vandalia, Ohio, Long Island College Hospital, Brooklyn, 1885, member of the Ohio State Medical Association, at one time bank president, aged 75, died, July 27.

Harry A. Oftel, Cambridge, Minn., Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1902, aged 55, died, August 10, of coronary sclerosis.

Lewis M. Bryson, Paradise, Pa., Jefferson Medical College of Philadelphia, 1879, member of the Medical Society of the State of Pennsylvania, aged 84, died, July 28, of coronary stenosis.

Woodbury F. Cleveland, Eastport, Maine, Hahnemann Medical College of Philadelphia, 1881, member of the Maine Medical Association, aged 78, died, September 14, of angina pectoris.

Robert Howell Baker, Watertown, Tenn., University of Nashville Medical Department, 1873, Pulte Medical College, Cincinnati, 1881, Civil War veteran, aged 87, died, September 29.

Arthur F. Schellschmidt, Red Bud, Ill., Hospital College of Medicine, Louisville, 1892, aged 64, on the staff of St. Clement's Hospital, where he died, September 17, of pneumonia.

Levi A. Van Pelt, Paola, Kan., Medico-Chirurgical College of Kansas City, 1900, county health officer and county coroner, aged 69, died suddenly, September 6, of heart disease.

Joshua Edgar Jeter, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1904, aged 54, was instantly killed, September 7, when he was struck by an automobile.

William J. Griffin, Seattle, Rush Medical College, Chicago, 1901, member of the Washington State Medical Association, aged 62, died, August 20, of cerebral hemorrhage.

Douglas Nebraska Harris, Prentice, Ill., Northwestern Medical College, St. Joseph, 1887, member of the Illinois State Medical Society, aged 80, died, September 8, of uremia.

John L. Moore, Richmond, Va., College of Physicians and Surgeons, Baltimore, 1886, served during the World War, aged 70, died, September 8, of coronary thrombosis.

James Welker Geist, Wilkes-Barre, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1890, aged 70, died, September 18, in a local hospital, of nephritis.

Robertson A. Whitaker, Dallas, Texas (licensed in Texas under the Act of 1907), aged 74, died, September 7, in a local hospital, of gangrene of the right lower extremity.

Frederick Anthony Hahn, Santa Fe, N. M., Harvard University Medical School, Boston, 1928, aged 31; died, September 6, when he fell from a third story porch.

Joseph Battle Philips, Middlesboro, N. C.; University of Maryland School of Medicine, Baltimore, 1903, aged 54, was found dead, September 21, of heart disease.

William Henry Kasten, Lansford, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; died, June 5.

James Napoleon Ketchersid, Hope, Kan., University of the City of New York Medical Department, 1873; aged 84, died, September 30, of cerebral thrombosis.

Frederick C. Senn, Oshkosh, Wis.; College of Physicians and Surgeons of Chicago, 1885; aged 79, died, September 19, of arteriosclerosis and mitral regurgitation.

Noah Welzy Murphy, Vincennes, Ind., Medical College of Indiana, Indianapolis, 1905, formerly a druggist, aged 56, died, August 28, of carcinoma of the liver.

Edmund L. Shirley, Apache, Okla.; St. Louis College of Physicians and Surgeons, 1887, Civil War veteran, aged 90, died, August 30, as the result of a fall.

George S. Dudley, New Brunswick, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1890, aged 68, died, September 16, of diabetes mellitus.

James Hervey Galloway, Roseland, La., Tulane University of Louisiana School of Medicine, New Orleans, 1914, aged 44, died, June 8, of heart disease.

George E. Andrews, Bay City, Mich., University of Pennsylvania School of Medicine, Philadelphia, 1887; aged 79, died, August 31, of chronic nephritis.

Burton W. Seymour, Jamestown, N. Y., University of Buffalo School of Medicine, 1884, aged 80, died, September 15, of acute dilatation of the heart.

Wylie Joseph Stewart, Coraopolis, Pa., Western Pennsylvania Medical College, Pittsburgh, 1900, aged 61, died, August 26, of coronary occlusion.

Jeremiah Calfer Wilson, Greenville, Ill., St. Louis College of Physicians and Surgeons, 1883, aged 74, died suddenly, September 9, of heart disease.

Joel Jasper Howell, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1884; aged 85, died, August 28, of chronic myocarditis.

John Robert Barnes, South Carrollton, Ky., University of Louisville School of Medicine, 1892, aged 76, died, September 14, of heart disease.

Rufus C. Pennywitt, Dayton, Ohio; Louisville (Ky.) Medical College, 1896; aged 62, died, September 18, in Manchester, of heart disease.

Fred Danziger, Chicago; University of Illinois College of Medicine, Chicago, 1929, aged 33, died, October 12, of carcinoma of the rectum.

Henry C. Mathis, Taylorsville, Ky., St. Louis Medical College, 1860, aged 98, died, September 2, of cerebral hemorrhage.

Charles F. Bush, Colquitt, Ga., University of the South Medical Department, Sewanee, Tenn., 1909, aged 46, died, August 14.

Mary Helen Thompson, Philadelphia, Woman's Medical College of Pennsylvania, Philadelphia, 1882, aged 80, died, August 3.

Arthur B. Woolner, Chattanooga, Tenn., Chattanooga Medical College, 1902, aged 65, died, July 27, in the Erlanger Hospital.

Emmett H. Bobbitt, Franklinton, N. C., University of Maryland School of Medicine, Baltimore, 1877, aged 81, died, July 30.

James Buchanan Pound, Bucklin, Mo., College of Physicians and Surgeons, Keokuk, Iowa, 1897, aged 62, died, July 23.

Jeremiah C. Ellsworth, Van Wert, Ohio, Homeopathic Hospital College, Cleveland, 1871; aged 85, died, July 14.

Adolph F. Schulz, Fort Wayne, Ind. (licensed in Indiana in 1897), aged 80, died, September 18, of heart disease.

Daniel O. Menasco, Whitehaven, Tenn., Memphis Hospital Medical College, 1891, aged 67, died, July 30.

Abner Walter Mann, Oak Grove, Mo., Missouri Medical College, St. Louis, 1883, aged 82, died, July 18.

Julian C. Carson, Frankfort, Ind. (licensed in Indiana in 1897), aged 72, died, July 27, of heart disease.

Elbert J. Lee, St. Louis (licensed in Missouri in 1881) Civil War veteran, aged 90, died, July 25.

Bureau of Investigation

THE GERMAN FRUIT SALTS FRAUD

H. Landgraf of Philadelphia is Debarred
from the Mails

For the past year or two Herman Landgraf of 1233 West Huntingdon Street, Philadelphia, has been selling through the mails what he has variously called "German Fruit Salts" or "Fruit Salts Biological Elektrolyt." On July 30, 1934, the Acting Postmaster General, on the recommendation of Judge W. E. Kelly, Solicitor for the Post Office Department, issued a fraud order debaring H. Landgraf from the use of the United States mails.

If one were to believe Mr. Landgraf, his panacea was good for practically every pathologic state to which the human body might be subject. So crudely was the nostrum exploited that it would seem that Landgraf was more ignorant than fraudulent. So little did he appreciate the inherent humbug involved in the sale of his "patent medicine" that he applied to the Council on Pharmacy and Chemistry of the American Medical Association for acceptance of his "Fruit Salts" in "New and Nonofficial Remedies." To quote *verbatim et literatim* from one of his letters to the Council:

"It is a biological method and theory to heal diseases with a specific diet which physiologically influences all diseases by dissolving physiologic, metabolic poisons, destroying bacteria, binding physiologic acids and by irritation of the finest blood vessel nerves, regulates the circulation.

"It creates electric currents splitting the molecules into Iones, which by physical oscillations produce oxygen, hydrogen, phosphorus and sulphurous Iones, which by friction produce electric currents and an artificial atmosphere. In this manner the sympathetic and parasympathetic nerves through reflexes are put into action and thus the disturbance to the blood vessels are eliminated, so that a cure can be accomplished of any disease."

The Council emphasized that one of the first requirements that physicians made before using a new remedy was a knowledge of its composition. Mr. Landgraf replied:

"Concerning your request for a quantitative statement, this cannot be furnished, it being part of the secret, personal process of the manufacture by the discoverer."

Later, however, Mr. Landgraf admitted that the composition of the "Fruit Salts Biological Elektrolyt" was:

Sodium citrate.....	19.5 per cent
Sodium tartrate.....	20.5 per cent
Sodium phosphate.....	25.9 per cent
Sodium sulphate.....	34.1 per cent

From this it appears that 60 per cent of the so-called "Fruit Salts" consists of a mixture of Glauber's salts and sodium phosphate—substances that by no stretch of imagination can be called salts derived from fruits.

In his literature Mr. Landgraf listed alphabetically some of the diseased states for which his "salts" were recommended. He named only 138 conditions, but prefaced the list with the statement: "If you cannot find listed what you are looking for, please write, it is impossible to name every disease on a circular"—which seems obvious. But the alphabetical list was a noble one, from Apoplexy, through Blood poison, Cancer, Diabetes, Epilepsy, Fistula, Glaucoma, Heart disorders, Impotence, Kidney stones, Leucemia, Milk leg, Neuritis, Paralysis, Rupture, Sciatica, Tuberculosis, Ulcers, Varicose veins and Whooping cough to Yellow jaundice. The names of diseases beginning with "X" and "Z" were omitted; they would doubtless be furnished on request.

Landgraf, by offering to pay fifty cents for the names of sufferers from diabetes and some other conditions should the victims purchase his nostrum, obtained mailing lists. A physician in a small town in Pennsylvania sent to the Bureau of Investigation a letter that a patient of his had received from Landgraf. The patient had a young son with diabetes. Landgraf's letter read in part as follows:

"I am told that you have Diabetes. I import GERMAN FRUIT SALTS, specialize in Diabetes producing PERMANENT RESULTS, overcoming conditions that doctors fail in, as for instance

STOP PAINS	STOP ITCHING
STOP GANGRENE	STOP BLINDNESS
STOP NUMBNESS	STOP HARD HEARING
STOP INSULIN	STOP AMPUTATION
HEAL SORE TOES	HEAL GANGRENOUS SORES OR OTHERS

"Doctors claim diabetic sores do not heal, Salts have healed the SEVEREST sores in 10 days to 4 weeks. Salts stop the use of Insulin which neither cures nor make sugar free, but may cause blindness, hard hearing, and will poison the whole organism, so stated by german medical authority, its use will cause irreparable damage.

"I enclose a circular showing a FEW OF HUNDREDS of cases, ALL HAVE BEEN TREATED BY DOCTORS WITHOUT SUCCESS.

"For details and proof RETURN THIS LETTER BY NECT MAIL."

The doctor who sent in the letter reported that the lad's father was "much worried" since his boy was receiving rational medical treatment. No wonder! Such pernicious falsehoods regarding the rational treatment of diabetes by means of insulin, while patently absurd to physicians, were not so obvious to the layman. Here again one must believe that Landgraf's quackery was actuated more through ignorance than malice. But, as Goethe has so well said: "Nothing is more dangerous than active ignorance."

[After this article had gone into the pages, the Bureau of Investigation received a letter from Dr. L. E. Baker of Espy, Pa., reporting that H. Landgraf had come to that town allegedly as an agent for the "Hilton Chemical Company," 2626 North 12th Street, Philadelphia. Signs have been put up at small stores reading: "DIABETES. Any Disease Relieved by New System of Medicine from Europe." The storekeepers have been instructed to refer prospective patients—or victims!—to the Hilton Chemical Company. This would appear to be Landgraf's method of attempting to circumvent the fraud order issued by the United States Post Office Department.]

Correspondence

URTICARIA DUE TO COLD

To the Editor:—Under current comment, September 29, you discuss physical allergy, noting the reporting of cases of urticaria due to cold in 1905 by Fraser and by Osler. I would call attention to an article on the etiology of urticaria by George Henry Fox in 1883 (*J. Cutan. & Ven. Dis.* 1:108, 1883).

He wrote: "Munchmeyer (*Berl. klin. Wchnschr.*, May 17, 1875) relates the case of a soldier who suffered from urticaria upon every exposure to a cold wind. It usually appeared in the form of three large circular wheals upon the cheeks and chin. Ungar (*Berl. klin. Wchnschr.*, Nov. 28, 1881) reports the case of a patient who, after a short stay in the open air, suffered from an extensive eruption of urticaria, followed in a few minutes by an attack of bronchial asthma. Upon return to a warm atmosphere, the shortness of breath gradually subsided and the urticarial wheals vanished."

It appears that observations of physical allergy, as manifested by urticaria due to cold, had found their way into medical literature at least thirty years before the reports of Fraser and of Osler.

RICHARD L. SUTTON JR., M.D., Kansas City, Mo.

PHOTOGRAPHIC ILLUSTRATION IN MEDICINE

To the Editor:—For a number of years I have paid particular attention to the illustrations that appear in textbooks and the various medical journals. Generally speaking, the standard of photographic illustrations in this country is low. This summer I reviewed one year's subscription of five standard medical journals for the quality of the photographs illustrating the articles.

From my observation of a total of 3,600 photographs which appeared in these journals I compiled the following statistics: 864, or 24 per cent of the illustrations, were poor; 1,218, or 34 per cent, were only fair; 1,518, or 42 per cent, were good or excellent.

I might mention that on looking over these illustrations I took into consideration the difficulty of photographing certain

clinical subjects and the usual loss of detail that is encountered in the preparation of cuts. I noticed many beautiful photographs of roentgenograms. However, I feel safe in saying that in general the illustrations showing roentgenograms had the poorest average of the various types of photographs studied. It was especially interesting and gratifying to note that articles issued from institutions in which members of the Biological Photographic Association are employed were illustrated by photographs of a decidedly better quality and invariably fell into the good or excellent class.

A letter of inquiry was sent to the editors of journals that were reviewed regarding their policy for the acceptance of photographic material for publication.

Each reply states that a high standard is maintained and that poor prints are often returned or the negatives requested so that better prints may be made. Considering the efforts on the part of the editors to publish only photographs of better quality, it is rather discouraging to note that only 42 per cent are only good or excellent. I fully appreciate the fact that no definite conclusion can be drawn from a study of one year's subscription. Nevertheless it affords a fairly good idea of the type of photographs that appear in the medical journals.

Why are the illustrations of a low standard? First, too many physicians who have little or no knowledge of the principles of photography are attempting to illustrate their own cases. I am fully aware of the fact that a great deal of very fine photographic work is being done by various members of the medical profession. However, these men are by far in the minority.

If medical men want to do this sort of work, they should take the time to learn to do it properly. Good medical photography is not a snap, snap proposition. It requires more than a clinical camera outfit. A broad knowledge of photography plus the skill to apply this information to biologic subjects is most essential. So far as helping to overcome this condition, I would suggest that whenever possible members of the Biological Photographic Association offer courses of instruction to groups of medical men who are especially interested in this work. Such opportunities present themselves particularly in medical schools and large hospitals.

During my last two or three years in the photographic department of the Yale Medical School, courses in clinical photography were given to the interns in pathology each winter and they proved highly successful. Similar courses have been carried on at the Veterans' Administration Facility, Hines, Ill.

The average physician should be more critical regarding the photographs that are to illustrate an article into which he has put long hours of exacting work.

Another reason for the poor quality of the pictures that are seen in medical journals is the fact that in many institutions it is assumed that because the x-ray technician deals with light, films and developer he naturally has all the qualifications of an expert clinical photographer. We have in the Biological Photographic Association men who are skilled experts in both x-ray work and biologic photography. However, this is an exception rather than the rule.

As far as I know, Mr. Carl D. Clarke of the University of Maryland was the first to mention the possibility of a school in which one could receive special training in biologic photography. If such an idea could be worked out satisfactorily, there is no doubt that it would be a great step forward, and as a result, the photographic illustrations would be considerably improved.

RALPH P. CREEER, Veterans' Administration Facility,
Hines, Ill.

Senior Clinical Photographer; President,
Biological Photographic Association.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CHRONIC APPENDICITIS

To the Editor.—I have under my care a newly married woman, aged 26, who has been complaining of pain in the right lower quadrant of the abdomen. This pain has been present almost daily for the past two months and at times there is some gastric upset without any vomiting accompanying the pain. Although the pain is quite severe, the patient is able to continue her work as a secretary. She has noticed that the pain is more severe after exercise and along toward evening. Examination reveals some tenderness on deep palpation over McBurney's point. Examination of the pelvis is negative save for a mild leukorrhea, which, the patient states, has existed since she was a child. Menstruation has been fairly regular, although it is sometimes a few days late and lasts only two or three days. There is no dysmenorrhea. A roentgenogram taken after the ingestion of an opaque meal showed a retrocecal appendix and the transverse colon markedly spastic. Would you please tell me the proper way to treat this case? Are all retrocecal appendixes pathologic? If so, what would be the proper treatment for a patient who refused operation? Would a spastic large bowel give this train of symptoms? Please omit name.

M.D., Connecticut.

ANSWER.—The symptoms are strongly suggestive of a subacute or so-called chronic appendicitis. Stomach symptoms are a frequent accompaniment.

The local tenderness over the region of the appendix is quite characteristic of a diseased appendix.

An important condition to differentiate in this case is a spastic colitis. As a rule, when the symptoms are due to a spastic colitis the tenderness is not localized over the appendix but is more diffuse, extending over the ascending colon, and in nearly all instances it is present over the sigmoid colon. In thin persons the sigmoid may be palpated and felt to be slightly rigid, thickened and definitely tender.

Both conditions may be present, but in the absence of more definite changes one would be inclined to treat a case showing tenderness over the sigmoid and ascending colon as an irritable bowel.

One should consider other conditions causing tenderness in the right lower quadrant and should look for kidney disorder, obstructing bands from so-called Jackson's membrane, a regional ileitis, omental bands, pelvic disease, and other conditions accessible through a muscle-splitting incision.

At present it is impossible to say that all retrocecal appendixes are pathologic, but they are frequently kinked and subject to stasis, fecaliths and consequently attacks of inflammation.

In this case one would believe that operation is indicated, with careful exploration through a muscle splitting incision. The risk in good hands is almost negligible.

Nonoperative treatment would consist of a diet that avoids irritation to the bowel and above all constipation. There should be plenty of well cooked or thoroughly ground vegetables with a well balanced diet. Liquid petrolatum may be of value.

The patient should be warned of the danger of an acute appendicitis and the great frequency of perforation and peritonitis within the first twenty-four or forty-eight hours, with its resulting high mortality.

URTICARIA AT MENOPAUSE

To the Editor.—Will you kindly tell me the relationship of the menopause to urticarial skin lesions and whether endocrine therapy is of any value? What is the status of autohemotherapy in the treatment of hives, and what is the best dosage and interval of treatment? Kindly omit name.

M.D., California.

ANSWER.—The ovarian deficiency at the menopause may lower the threshold of irritability so that urticaria may result from slight causes, less than sufficient to evoke it at other periods of life. On the other hand, according to Engelbach (Endocrine Medicine, Springfield, Ill., and Baltimore, C. C. Thomas, 1932), urticaria may be a symptom of nearly any of the forms of endocrine excess. It was part of the clinical picture in 20 of 351 cases of thyroidism, 27 of 492 cases of pituitarism, 5 of 160 cases of thyropituitarism and 23 of 504 cases of gonadism. Women with a preceding endocrinism do not respond normally to the menopause. The symptoms of this change in such patients are not caused by a simple reduction in ovarian activity. To interpret them the preceding endocrine abnormality must be determined. This requires careful study, and after the correct diagnosis is made the response to treatment may be slow or unsatisfactory in such old cases.

Autohemotherapy is often successful in terminating chronic urticaria for which no cause has been found. The dosage varies ordinarily from 5 to 20 cc., at five day intervals. Immediately after the blood has been drawn it is injected deeply into the buttock. A slight febrile reaction after the first or one of the early injections need not cause surprise.

CEREBRAL INJURY AND SUGAR METABOLISM

To the Editor:—Last November a man, aged 48, was taken to the hospital suffering from a sudden attack of unconsciousness, which was diagnosed as spontaneous subarachnoid hemorrhage. Spinal tap showed blood and xanthochromia. He had a chronic hypertensive condition. There were no especially significant urinary changes. There was no sugar in the urine. The blood sugar was 102 mg. per hundred cubic centimeters of blood. After about ten days his condition improved and he went home feeling quite well. There was no paralysis. Three weeks ago a urinalysis showed no marked abnormalities. A week ago he again became unconscious. A period of about two hours elapsed from the onset until unconsciousness was complete. He had passed urine early that morning and nearly two pints was removed by catheterization from a distended bladder. Breathing was stertorous. The reflexes were lowered. The pupils were medium, fixed and unequal. A spinal tap withdrew 6 cm. of bloody fluid under moderate pressure, 12 mm. of mercury. The blood pressure was 270 systolic, 145 diastolic. There was no sugar in the urine. The blood sugar was 275. No diacetic acid was reported. The same diagnosis was made as for the first attack. The patient died about twelve hours after the onset of the attack without regaining consciousness. Because of the history and absence of diacetic acid I am assuming that the high blood sugar was the result of cerebral irritation from the hemorrhage. If it was of cerebral origin, what effect if any would the high blood sugar have on the progress of the case and how, if at all, should treatment be modified by its presence? Is there any use for insulin in this condition? Also dextrose? Please omit name.

M.D., Pennsylvania.

ANSWER.—Cerebral injury, if it affects the subthalamic regions of the brain, is frequently accompanied by hyperglycemia and glycosuria. As a rule the disturbance of carbohydrate metabolism produced by this means is transient. There is no evidence that the supply of insulin is disturbed, and it is presumed that the effect like that following puncture of the floor of the fourth ventricle, the Claude Bernard procedure, is to stimulate the glycoscretory sympathetic fibers to the liver. However, injected insulin will counteract the resulting glycolysis and thus reduce the blood sugar to normal and stop the excretion of sugar.

It is also possible in cases of severe hypertension to have a hyperglycemia and some glycosuria without there being any cerebral injury. This, possibly, is to be attributed to overfunction of the suprarenals.

In neither of these conditions is the control of hyperglycemia and glycosuria of much importance clinically. At worst, the diabetic conditions resulting are not severe or accompanied by much, if any, ketosis. It is not considered probable that the hyperglycemia in this patient affected the progress of the case or that its treatment would have modified the course.

FOOD ABSORPTION FROM RECTUM

To the Editor:—I should like to know to what extent dextrose (5 per cent solution), peptonized milk and whisky are absorbed from the rectum. References to the literature will be appreciated. Kindly omit name and address.

M.D., New York.

ANSWER.—The question of the absorption of dextrose from the rectum is still a controversial matter (Collens, W. S., and Boas, L. C.: Absorption of Dextrose by Rectum, *Arch. Int. Med.* 52:317 [Aug.] 1933. Bauer, J., and Monguio, J.: Sugar Metabolism in Relation to Resorption of Sugar Administered by Rectum, *Klin. Wchnschr.* 11:1820 [Oct. 29] 1932. Scott, E. L., and Zweighaft, J. F. B.: Blood Sugar in Man Following Rectal Administration of Dextrose, *Arch. Int. Med.*, 49:221 [Feb.] 1932. Julesz, M., and Winkler, E.: Effect of Rectal Administration of Concentrated Dextrose Solutions on Blood Sugar, *Ztschr. f. d. ges. exper. Med.* 80:823, 1932. Perusse, G. L.: The Solution of Choice in Proctoclysis, *Gynec. & Obst.* 54:770 [May] 1932). The amount absorbed is certainly not great enough to be of much importance for purposes of nutrition. The use of peptonized milk is no doubt an error (Van Noorden, Carl: Ueber rectale und parenterale Ernährung, *Therap. Halbmonatsh.* 34:1 [Jan. 1], 40 [Jan. 15] 1920), for the fat is not absorbed, nor the lactose to any great extent. The peptone is probably the most important ingredient, and this might more rationally be administered in 10 or 20 per cent solution in physiologic solution of sodium chloride. Alcohol is quite readily absorbed from the rectum, best from a 10 per cent solution (Hauzlik and Collins: *J. Pharmacol. & Exper. Therap.* 5:185, 1913).

POSTGONORRHEAL INFECTIONS

To the Editor:—A man, aged 35, presented himself six months ago with the complaints of frequency, nocturia, backache and a clear urethral discharge. He stated that for the six weeks prior to that he had had a thick yellow discharge and burning on urination. He had received no treatment for this condition. On examination the prostate was enlarged and extremely painful, but soft. Smears made were negative for the gonococcus. He was given prostatic massage, gently at first, and then gradually posterior instillations were added. Preparations so used were silver nitrate, strong silver protein and neosilvol. All the symptoms gradually left, and he is now feeling very well again. Only one thing is still not as I wish it. His urine, only the first specimen passed, is loaded with small threads of mucus and always contains six or eight large threads. The urine is clear and normal otherwise. I have been massaging the prostate and instilling neosilvol up to 10 per cent and silver nitrate up to 0.4 per cent every other day, but the threads persist. The prostate, although now of normal size, is still a bit tender. After a month's rest he returned with no improvement. Can you suggest any further treatment to clear up the urine? Please omit name.

M.D., Missouri.

ANSWER.—It is not uncommon for a patient at this stage to have shreds containing gonococci with the condition of a latent or carrier-like state, although usually but not always there is clinical activity after the instillation of silver nitrate. Also, about 10 per cent of postgonorrheal infections are due to colon bacilluria and respond favorably, as a rule, to high acidification as obtained by the ingestion of from 4 to 6 Gm. of ammonium chloride daily, in divided doses, combined with the administration of methenamine or methenamine salicylate, from 2 to 4 Gm. daily. Finally, many patients with the condition described will show on urethroscopic examination infection of dilated prostatic ducts which, if present, require eradication by electrical excision or cauterization transurethrally.

VINCENT'S INFECTION OF MUCOUS MEMBRANES

To the Editor:—In Vincent's angina do ulcers develop on any other membranes than the membranes of the mouth or throat? Are the organisms found in cases of infection in the vagina? All the books that I have which make reference to Vincent's infection speak only of the mouth and throat as the location of the ulcers.

C. L. PEARCY, M.D., Salem, W. Va.

ANSWER.—Fusospirochetal (Vincent's disease) infections of parts of the body other than the oral cavity have been described repeatedly. Davis and Pilot (Studies of Bacillus Fusiformis and Vincent's Spirochete, *THE JOURNAL*, Sept. 16, 1922, p. 944) reported a number of cases of a gangrenous condition of the penis presumably caused by these organisms. Cases of putrid gangrenous abscesses of the lungs and brain are even more numerous in the literature. A recent monograph (Smith, D. T.: Oral Spirochetes and Related Organisms in Fusospirochetal Disease, Baltimore, Williams & Wilkins Company, 1932) discusses this subject in great detail. According to Smith, most of the reported fusospirochetal infections in the female genital region are of the gangrenous or noma type, rather than ulcerative, and are relatively rare. On the other hand, "fusiform bacilli and spirochetes are commonly found about the clitoris of normal women but are usually absent in smears from the vagina. Women of the prostitute class become carriers of the infection." Balanitis in the male may be traced in many instances to cohabitation with women in the last group.

BCG INOCULATIONS AGAINST TUBERCULOSIS

To the Editor:—It is my understanding that the Chicago Board of Health has some method of inoculating against pulmonary tuberculosis. I have been unable to find in any of the recent medical journals information concerning any such remedy which is certain enough to be used in as massed quantity as the Chicago Board of Health seems to be going to use. Possibly I have overlooked this news, but if possible would you kindly send me such information as may be at hand concerning the treatment as intended to be used by the Chicago Board of Health.

GEORGE H. WATERS, M.D., Des Moines, Iowa.

ANSWER.—The question was referred to the president of the Board of Health of Chicago, who writes: "The Chicago Board of Health is not using any method of inoculation for the prevention of pulmonary tuberculosis. It is evident that this inquiry refers to the contemplated use of BCG vaccine by the Municipal Tuberculosis Sanitarium. At present there is no unanimity of opinion as to the value of BCG vaccination nor is the evidence absolutely definite that the vaccine may not have certain dangers. S. A. Petroff, director of research and clinical laboratory of the Trudeau Sanatorium, Trudeau, N. Y., seems to be the chief opponent of this method of vaccination in the United States. Dr. William Park evidently believes that it may have value in protection of infants in contact with tuberculous parents. The board of health could not consider the use of this method until there is some general agreement as to its value and safety."

BLOOD IN SEMEN

To the Editor:—A man, aged 28, single, in the past two months has noticed blood in the semen, detected in removing a condom after intercourse. The amount is small but sufficient to notice. No gross blood appeared in the urine voided a few minutes later. He states that an anterior gonorrheal urethritis occurred eight years ago, which responded to treatment in three weeks and was without complications and recurrences. The Wassermann and urine tests are negative. The prostate and entire urinary system are entirely normal so far as I can tell. A prostatic smear is negative for gonococci. Please omit name if published.

M.D., Tennessee.

ANSWER.—Blood in the semen may be due to a number of causes: (1) tuberculosis of the lower end of the genital tract; (2) stones in the seminal vesicles; (3) papilloma or other neoplastic growths in the posterior urethra in the region of the ejaculatory ducts; (4) granulations in the lower end of the genital tract. A study directed to these parts will usually establish a diagnosis. The differentiation can be made only by a combined laboratory and visual examination of the parts mentioned.

ROENTGEN TREATMENT OF TONSILS

To the Editor:—Will you kindly tell me the merits of shrinking the tonsils with x-rays as compared with regular tonsillectomy? Kindly omit name.

M.D., Georgia.

ANSWER.—Some years ago there was considerable furor regarding applications of the x-rays in the endeavor to remove the tonsils. As a matter of fact the tonsils were diminished in size owing to changes in the lymphoid structures, but the epithelium lining the crypts was not destroyed. The tonsils themselves were merely diminished in size but not caused to disappear. Sterilization of the crypts was effected, but it lasted for only a few days after irradiation. In a word, the recurrence of tonsillitis was not prevented and many patients had to be operated on later in the usual manner. Roentgen treatment of the tonsils is no substitute for tonsillectomy. If chronic tonsillitis is present, complete removal of the tonsils by one method or another is the proper procedure.

POSTOPERATIVE CARE OF CUTANEOUS CARCINOMA

To the Editor:—A woman, aged 45, presented a small epithelial growth, the size of a pea, on her forehead. I removed the growth under local anesthesia, taking out some normal surrounding tissue to make certain that I had removed it completely. Microscopic examination showed a cornified epithelial surface; subjacent structures show nests of epithelial cells, with slight variation of size and shape and occasional mitotic figures. The microscopic diagnosis by the pathologist was basal cell carcinoma. Please advise me whether high voltage roentgen therapy is indicated now in this type of case. Please omit my name and address if this is published.

M.D., Maine.

ANSWER.—When dealing with small superficial basal cell epitheliomas that have been excised, the consensus is that it is not necessary to irradiate the area. It is advisable, however, to inspect the area about twice a year for a few years.

TREATMENT OF SYPHILIS

To the Editor:—In "Standard Treatment Procedure in Early Syphilis" and in the part corresponding to a "Scheme of Treatment for Early Syphilis" (THE JOURNAL, April 21), I find the indication of 20 centigrams of bismuth. I wish to know whether this refers to a bismuth salt or to metallic bismuth. I also wish to know the doses of potassium iodide and of the mercuric ointment mentioned in the part to which I refer. It also would interest me to obtain the schedule of treatment referring to it.

J. E. CAVELIER, M.D., Bogota, Colombia.

ANSWER.—The 20 centigrams of bismuth refers to a bismuth salt, the salicylate. The doses of potassium iodide suggested are an average of 1.3 to 2 Gm. (from 20 to 30 grains) three times daily. The dose of mercurial ointment is 4 Gm. of the 50 per cent U. S. P. ointment. The instructions are given at the rate of six each week, with the usual technic of application.

TREATMENT OF BEE STINGS WITH EPINEPHRINE

To the Editor:—In the answer to the query as to the effective treatment for bee stings, in THE JOURNAL, September 22, p. 937, the June 1934 issue of *Bees and Honey* is cited as recommending the use of epinephrine intramuscularly or intravenously in a dosage of 1 cc. of 1:1,000 solution. Having had experience in the intravenous use of epinephrine 1:1,000 in peracute attacks of bronchial asthma, I would suggest that its use intravenously in the dosage recommended would be highly dangerous. If the emergency is such that epinephrine 1:1,000 must be used intravenously, it should be used in small doses of from 0.05 to 0.20 cc., well diluted with saline solution and injected very slowly.

JEROME GLASER, M.D., Rochester, N. Y.

OREGON: *Basic Science.* Portland, Nov. 17. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. A. Earle Boozier, 505 Saluda Ave., Columbia.

TEXAS: Galveston, Nov. 20-22. Sec., Dr. T. J. Crowe, 918 Mercantile Bank Bldg., Dallas.

VIRGINIA: Richmond, Dec. 12-14. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

WEST VIRGINIA: Martinsburg, Oct. 29-31. State Health Commissioner, Dr. Arthur E. McClure, Charleston.

WISCONSIN: *Basic Science.* Milwaukee, Dec. 15. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

Louisiana June Report

Dr. Roy B. Harrison, secretary, Louisiana State Board of Medical Examiners, reports the written and practical examination held at New Orleans, June 7-9, 1934. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and three candidates were examined, all of whom passed. Five physicians were licensed by reciprocity. The following schools were represented:

Book Notices

Summary of Pennsylvania's Poor Relief Laws Affecting Care of Indigent Sick. A Digest of Laws and Practices with Supplements Discussing the Pennsylvania Plan for Emergency Medical Service to Those on Unemployment Relief and Pennsylvania's Work Relief Compensation Fund. Paper. Pp. 100. Harrisburg: Medical Society of the State of Pennsylvania, 1931.

In a concise, well prepared, handy volume, the Medical Society of the State of Pennsylvania conveys to the reader facts, experiences and suggestions pertaining to the medical phase of relief to the indigent. The booklet was prepared for distribution to county poor authorities, social workers, county medical society officers and others interested in providing minimal adequate medical service to the indigent. It brings together, for easy reference, county reports giving the type of organization responsible for poor relief, the methods used in providing medical care, the amount paid for medical services to the indigent, and suggestions for improvement of these services. A section is devoted to a digest of the poor relief laws and practices of Pennsylvania in which important definitions and procedures are clearly set forth.

It is logical that in connection with the discussion of general poor relief some attention be given to the recent development of emergency medical service to those on unemployment relief. The Pennsylvania plan, including rules and regulations, fees and suggestions for its operation, is given in detail. An interesting and instructive table on page 94 gives for five counties separately, and for the entire state, the extent and costs of medical services and the ratio of these services to the number of relief cases. A brief discussion of medical service under Pennsylvania's Work Relief Compensation Fund indicates the interest that is being taken in the medical phase of workmen's compensation by the Medical Society of the State of Pennsylvania.

A compilation of information such as that contained in this publication is sure to assist materially in improving the general understanding on an important phase of medical practice. With the facts thus clearly set forth it should be possible more easily to effect improvements in the medical services to the indigent wherever such improvements seem indicated. A similar compilation of state poor laws and practices in other states would be a valuable assistance to those who are interested in and responsible for this work.

Thérapeutique médicale. VII: Vaisseaux et reins. Par M. Loeper. Avec la collaboration de MM. A. Lemaire, M. Debray, A. Zimmern, M. Villaret, Pasteur Vallery-Radot et J. Cottet. Paper. Price, 50 francs. Pp. 339, with 26 illustrations. Paris: Masson & Cie, 1934.

This is the seventh volume published by the chair of therapeutics of the Medical Faculty of Paris, under the leadership of M. Loeper; it deals with the blood vessels and the kidneys. Like the other volumes of this series, it is the result of the collaboration of a number of authors. One might deplore the occasionally uncritical display of erudition, which, starting with premises not definitely established, and probably erroneous, builds on this a program of action that is highly logical but unfortunately suffers from the fault that it does not accomplish the result. Thus Loeper, writing on arteriosclerosis, concentrates the fire of his heavy therapeutic artillery on the calcium and the cholesterol deposited in the diseased vessels, as though these chemical bodies, instead of their presence being the result, were the cause of the changes in the blood vessels. He proposes a low calcium and low cholesterol regimen, "detransfusing" medicaments, such as sodium silicate and sodium iodide, and, because calcium precipitates in an alkaline medium, the administration of phosphoric and lactic acids, apparently oblivious to the fact that the bones furnish an almost inexhaustible mine of available calcium that is actually tapped by acidifying the system. He has great faith in tincture of garlic (50 drops daily) and still more especially in its active principle, diallyl disulphide (0.02 Gm. in 1 cc. of oil), which is quite powerful in temporarily reducing blood pressure. Unfortunately, the transient effect of these rather painful injections cannot be expected to produce any important impression on the course of arteriosclerosis. Obviously, in therapeutics as in many other ways the French, with their therapeutic optimism, are diametri-

cally opposite in their tendency to their hereditary enemies, the Germans, with their therapeutic nihilism. Which is the better awaits the decision of the question as to whether it is better to have a "doubtful remedy than none" or "better no remedy at all than a doubtful one." Loeper has a good word to say for crataegus (Hawthorn berries, fluidextract 0.3 cc. twice daily) as a remedy to calm cardiac excitability in patients with a tendency to angina pectoris. In arterial hypertension, acetylcholine is spoken of along with the nitrites and yohimbine, which latter is shown to be capable of increasing the duration of the fall in blood pressure produced by acetylcholine. The indications of general and local bloodletting are discussed. The diuretics are taken up under two headings: the extrarenal, including water, salts, and digitalis bodies, and the renal diuretics, with the xanthine series, the mercurials and tincture of onion. The methods of treating nephrolithiasis, of hematuria and of renal tuberculosis are all taken up in a most practical manner. There is a chapter on urinary antiseptics. Kidney substance is believed to be a remedy of possibly special value in the anemia of kidney disease, though in other anemias it is undoubtedly inferior to liver. The book concludes with a symposium on the dietetics and the physical therapy of these diseases, including—as is the custom with European works of this kind—an evaluation of the national mineral spring resources, a matter in which we of this country are sadly remiss.

The Prospective Mother: A Handbook for Women During Pregnancy. By J. Morris Simons, M.D., Professor of Obstetrics and Gynecology, University of California. Third edition. Cloth. Price, \$2. Pp. 311. New York & London: D. Appleton-Century Company, Inc., 1934.

In the present edition, which appears thirteen years after the second edition, the chief changes include the hormone tests for the diagnosis of early pregnancy, the value of the x-rays for greater accuracy of diagnosis, new treatments for the ailments of pregnancy, the gain in weight during pregnancy, and the more recent methods for the relief of pain during labor. The author accurately and in simple language answers all questions that women generally ask during pregnancy. This book explains what goes on not only in the uterus but in the entire body during gestation. The advice given is helpful and will allay the fears many women have of the ordeal of childbirth. The technical terms used throughout the book are defined in a glossary at the end. A few minor criticisms may be mentioned. Among the methods for reviving a new-born child, the author advocates dipping the child alternately into warm and cold water. The latter may prove harmful to some babies. Simons speaks of a "final examination" after delivery. This term should not be used, because it is a mistake to give women the impression that the examination made six or eight weeks after a baby is born is the final contact with their physician until another pregnancy supervenes. Repeated visits are particularly important for women who have had toxemia, nephritis or other complications during pregnancy, but even women who have had no complications should visit a physician at least once a year after a child is born. The author uses the terms caesarean and anaesthesia instead of the simplified spelling. Without doubt the present edition, like the two previous ones, will prove to be highly popular with prospective mothers.

Essays on Chronic and Familial Syphilis. By Griffith Evans, M.A., D.M., F.R.C.S., Hon. Surgeon, Caernarvonshire and Anglesey Infirmary. Cloth. Price, \$3. Pp. 91, with 13 illustrations. Baltimore: William Wood & Company, 1932.

This series of nine papers is in part a collection of previous journal publications and the essays awarded the gold medal of the Hunterian Society in 1932. It deals with that "penumbra of doubt" at the confines of established diagnostic and clinical syphilology which deserves sincere consideration as knowledge of the pathologic mechanisms of the disease widens under the granular stage concept and the observations and opinions of Warthin. The leading topics are syphilis and nervous dyspepsia, and syphilis as a factor in chronic conditions of the abdomen, in nervous dysphagia, in anemia and glossitis with dysphagia, in finger nails and tongues, and in carcinoma. The author's familiarity with recent literature on syphilis is noteworthy and pleasing. Some of the applications have the overbalanced quality of the French fourth generation school (syphilis héréditaire larvée). The pitfalls of nonspecific effect in therapeutic

testing seem largely disregarded. As a summary of impressions that often press on the syphilis-alert clinician yet preserve a ghostly intangibility and a defiance of exact analysis, this little book is a thought-provoking and interesting contribution. Its defiance of the negative Wassermann reaction is timely. As the comment of a surgeon on the borderland of what is too often a sturdily ignored field when operative considerations claim the stage, it is in a happy sense unusual.

Ergebnisse der gesamten Tuberkuloseforschung. Herausgegeben von H. Assmann, H. Beltzke und H. Braevning. Band VI. Paper. Price, 60 marks. Pp 736, with 107 illustrations. Leipzig: Georg Thieme, 1934.

This book is divided into eleven parts, each written by a different author. The work is presented in logical sequence, beginning with the allergy that results from the first attack with tubercle bacilli, as well as the tuberculous focus itself. A discussion of the literature on primary tuberculosis precedes the presentation of material. This chapter is beautifully illustrated with x-ray films, which show all the stages of primary pulmonary tuberculosis from the inflammatory area about the focus to the formation of Ghon tubercles with calcium in the hilar lymph nodes. For this type of tuberculosis the author gives a good prognosis. In the discussion of the secondary infiltration he points out that the prognosis is not so favorable. Good illustrations of miliary tuberculosis and descriptions of tuberculous meningitis are presented. One chapter is devoted to the pathologic anatomy and in another there is an extensive discussion of hematogenous tuberculosis, which includes almost all the organs that may be involved. Various phases of surgery of the chest are presented by Roloff and by Sauerbruch and Fick. These chapters are profusely illustrated with drawings and reproductions of x-ray films, showing the results of phrenic exeresis and all modern surgical procedures. One chapter is devoted largely to rehabilitation, in which attention is called to the various kinds of work tuberculous patients are capable of doing. Some space is given to a discussion of the Potts Memorial Hospital of New York for that purpose. Other schemes, such as that at Papworth village, are fully discussed. Finally, a part is devoted to pleurisy by J. Adolph Frederiksen. In this chapter, all forms of pleurisy are discussed. Each part of this volume contains an extensive list of references. The long index impresses on one the large number of subjects covered.

Medicine in Persia. By Cyril Elgood, M.D., M.R.C.P. No. XIV, Clio Medica: A Series of Primers on the History of Medicine. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$1.50. Pp. 105, with 11 illustrations. New York: Paul B. Hoeber, Inc., 1934.

German Medicine. By W. Haberling M.D., Professor of the History of Medicine, Academy of Düsseldorf. Translated by Jules Freund, M.D. No. XIII, Clio Medica: A Series of Primers on the History of Medicine. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$1.50. Pp. 160, with 9 illustrations. New York: Paul B. Hoeber, Inc., 1934.

Japanese Medicine. By Y. Fujikawa, M.D. With a chapter on the Recent History of Medicine in Japan by Kageyas W. Amano, M.D. Translated from the German by John Rührich, M.D. No. XII, Clio Medica: A Series of Primers on the History of Medicine. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$1.50. Pp. 114, with 8 illustrations. New York: Paul B. Hoeber, Inc., 1934.

These three volumes are part of an extensive series of works on the history of medicine, which is being developed by the Hoeber Press.

The medical history of Persia begins with the fourth of the kings of Persia. The earliest references are to surgery and the use of anesthesia. Darius had Egyptian physicians, but it was to a Greek that he owed the saving of his leg. Dr. Elgood, the author, was himself physician to the British legation in Persia and he writes with a fine understanding of Persian tradition. His consideration takes up the story in chronological order, bringing the account down to 1927. It is his conclusion that Persia has played a glorious part in history but that in recent years has been only an imitator.

The story of German medicine is told by the professor of the history of medicine in Düsseldorf. He begins with a modest preface in which he points out that few phases in the history of medicine were created by the Germans but that German medicine must be correlated with the developments of medicine throughout the world. He also takes up the story of medicine chronologically, listing the many great names in the history of German medicine. His book was written in October 1933, yet

he does not fail to give full credit to the tremendous contributions of Jewish physicians to medicine in Germany. In bringing his story down to date he perhaps wisely avoids any consideration of the peculiar trend which German medicine has taken in the last year. Two deeply significant paragraphs are found in his concluding pages:

The financial status of the medical profession became much weakened in 1883 by the introduction of the compulsory public sickness insurance (Krankenkasse). The physician's salary for the immense amount of work required under this system is most inadequate; the insurance covers a large part of the population: workmen, clerks and their families, and so on. At first the insured persons did not have the privilege of choosing their physicians but as a result of the efforts exerted by the "Verbande der Ärzte Deutschlands" this has been changed and now the patients do have the privilege of selecting their physicians.

In 1901 an unfortunate change was made in medical education over the protest of the medical profession. It is now no longer required to finish the gymnasium in order to be admitted to the medical school, thus lowering the general educational level of physicians. The number of medical students has increased excessively, and the number of female students has doubled since the war (female students were first admitted in 1898).

The book by Kujikawa is an expansion of a short history of Japanese medicine written in 1911, to which is added an essay bringing the history of medicine in Japan down to the present. The book is so condensed as to represent practically a chronology, which indeed is repeated in a special appendix. The concluding chapter on the recent history of Japanese medicine points out how great has been the Japanese contribution and how much it depends on the German medical education which most Japanese leaders had in the last generation. There are at present twenty-seven medical schools, including two for women, in Japan. There are eighteen class A medical schools, of which fifteen are under the control of the department of medical education.

The Anaemias. By Janet M. Vaughan, D.M., M.R.C.P., Assistant Clinical Pathologist, the Royal Northern Hospital. With notes on Normal and Pathological Erythropoiesis. By Hubert M. Turnbull, D.M., F.R.C.P., Director of the Bernhard Baron Institute of the London Hospital. Cloth. Price, \$4. Pp. 248, with 24 illustrations. New York & London: Oxford University Press, 1934.

The author has attempted to review the present knowledge concerning the various forms of anemias and, in doing so, has successfully embodied all the pertinent data and information available at the time. H. M. Turnbull has contributed careful, intimate descriptions of the anatomy of normal erythropoiesis and of the pathologic anatomy of some of the anemias. The first chapter is devoted to discussion of the normal standard values and of normal erythropoiesis. To the reader it seems ambiguous to edit "mean corpuscular volume" and "mean corpuscular hemoglobin" as topics 4 and 5 respectively under the heading of "Infants" (page 7), for the standard figures given apply to the older and adult groups. Based on their etiology, the anemias are classified into four large groups: dyshematopoietic, posthemorrhagic, hemolytic and, finally, the unclassified anemias. The different forms of anemia are then discussed according to synonyms, definition, geographic distribution, race, sex, age hereditary factors, symptoms, clinical signs, blood picture, van den Bergh reaction, gastric analysis, pathologic anatomy, treatment, etiology and differential diagnosis. The authors believe that "leuko-erythroblastic anemia," a designation which they apply to the form occurring in carcinomatosis with deposits in the bones, in myelomatosis, in osteosclerosis and in Cooley's erythroblastic anemia, is not to be ascribed to crowding out of hematopoietic marrow by abnormal tissues; rather, they are inclined to believe that it may be a deficiency anemia. Acholuric jaundice is discussed at considerable length, twenty pages being devoted to it. Detailed description of the pathologic anatomy with necropsy reports on the marrow in six cases forms a large part of this section. Although the author considers liver therapy valueless, and while splenectomy remains the treatment of choice, recent reports point more favorably to the virtue of liver extract in cases in which splenectomy is contraindicated. Photomicrographs of the blood and of the marrow are conspicuous by their absence. To the general practitioner or to one not well grounded in hematology, such additions would prove of great assistance and would enhance the usefulness of this work. On page 29, discussing hypochromic anemia of infants, the author says "From experimental observations . . . it would appear that the

presence of anemia in the mother on a natural diet deficient in factors essential for erythropoiesis, especially iron, results in anaemia in the offspring." In man, however, Strauss and Castle (*Am. J. M. Sc.* 185:539 [April] 1933) found that, no matter how anemic the mother is, the infant is born with normal hemoglobin and a normal erythrocyte count. Notwithstanding these few critical remarks, the author has indeed achieved her objective in an admirable fashion and has presented this great mass of literature in a concise, easy, lucid style. This work may be considered a worthy contribution to the field of hematology.

Surgery of a General Practitioner. By Arthur E. Hertzler, M.D., Chief Surgeon, Halstead Hospital, and Victor E. Chesky, M.D., Chief Resident Surgeon, Halstead Hospital. Cloth. Price, \$10. Pp. 602, with 472 illustrations. St. Louis: C. V. Mosby Company, 1931.

The authors aim to reduce treatment to its simplest terms, recommending one time-tried measure for each lesion. They have paid special attention to the early recognition of lesions that may later become malignant. The contents include discussions on wounds and hemorrhage, general infection, non-suppurative lesions, traumatic local infections, lesions of the scalp and cranium, diseases and injuries of the face, nose, nasal pharynx, trachea, ears, mouth, jaws, tongue, regions of the neck, chest, mammary glands, anal region, male and female genitalia, superficial injuries of the extremities, tumors of the extremities, infection, deformity, vascular lesions, gangrene and ulcers. Part III includes general surgical therapy; namely, surgical technic, closure of wounds, bandaging and general therapeutic measures. The illustrations are well chosen and well reproduced. The authors' statement that sciatica is a painful disorder of the sciatic nerve which has nothing to do with the sacro-iliac joint is definitely open to question. No mention is made of serum in the treatment of gas gangrene. The authors state that when the general practitioner cared for the ailing public there was no complaint about the high cost of hospital care. They have tried to make the book a practical one for the general practitioner.

L'opération de Bassini pour la guérison radicale de la hernie inguinale. Par le Docteur Attilio Catterlina, professeur de médecine opératoire, Université de Gênes. Cloth. Pp. 57, with 16 illustrations. Paris: Librairie Félix Alcan, 1934.

This monograph is lavishly illustrated with large colored plates, which were painted by Dr. Orazio Gaigher. The unusual combination of a surgeon able to paint has given a striking series of illustrations. The work consists solely of a description in minute detail of the technic of the Bassini operation for hernia. The author was a former pupil of Bassini and can speak with authority on his original technic, which has been modified only slightly. These modifications consist first of the resection of the covering of the cord in order to permit tighter closure of the ring. The only other departure from Bassini's original operation consists of the section of the transversalis fascia in the floor of the canal. In the text this is described as sutured down to Poupart's ligament, although in the illustrations the stitches are not shown to include the sectioned transversalis fascia. In the last twelve pages of the book there is a discussion of various complications of hernia or scrotal abnormalities that may be encountered when the inguinal canal is laid open and the operative measures taken for their cure. While this book is a valuable contribution to the library of the specialist, one cannot help but deplore the undue emphasis on the Bassini operation, which in the opinion of many surgeons today requires considerable modification to meet all the demands in the repair of various pathologic conditions encountered in different sorts of hernia.

Security Analysis. By Benjamin Graham, Investment Fund Manager; Lecturer in Finance, Columbia University, and David L. Dodd, Assistant Professor of Finance, Columbia University. Cloth. Price, \$5. Pp. 725. New York: Whittlesey House, McGraw-Hill-Book Company, Inc., 1934.

This is an interesting book of its type, and the authors appear to know their business. One of them seems to be experienced on the practical and the other on the theoretical side of finance and they have blended their ideas into a logical and coherent whole. They treat investment principles for all types of securities, from the best grades of government bonds down to the most speculative of common stocks. Also the book is replete

with examples that back up their recommended standards of safety. Further, an attempt is made to show where the information needed for proper analyses may be found, and to give the reader some facility in the interpretation of balance sheets and income statements. To condense this material into a single volume, it was apparently necessary to assume that it would be read by those who have at least some knowledge of finance. Consequently, while the uninitiated may find in the book a good background for the discussion of securities, they must not hope that it will obviate the need of a consultant trained in this field. Probably the professional analyst will feel about this book much as the medical men felt about the "doctor book" so popular some years ago; in certain circumstances, a little knowledge is more dangerous than no knowledge at all.

A Textbook of Bacteriology with a Section on Pathogenic Protozoa. The Application of Bacteriology and Immunology to the Etiology, Diagnosis, Specific Therapy and Prevention of Infectious Diseases for Students and Practitioners of Medicine and Public Health. By Hans Zinsser, M.D., Professor of Bacteriology and Immunology, Harvard University Medical School, and Stanhope Bayne-Jones, M.D., Professor of Bacteriology, Yale University Medical School. Seventh edition. Cloth. Price, \$8. Pp. 1226, with 174 illustrations. New York & London: D. Appleton-Century Company, 1934.

It will repay any one to read the nineteen page outline of the history and scope of bacteriology that is the opening chapter in this book. It takes one as it were to a mountain peak from which one sees the most prominent discoveries in this field of science without having the attention drawn to myriads of technical details. It takes one back to ancient days, when the rising of bread and the transformation of grape juice into wine excited wonder. It leads then to mere opinions and theories of the causes of disease, some of which later were proved correct, following the discovery of the compound microscope by Jansen in Holland and Galileo in Italy, early in the seventeenth century. Then Leeuwenhoek discovered bacteria and Pasteur completed his studies on fermentation and established the principles of scientific investigation, which have influenced research ever since. Then came the discoveries of Koch in Germany and of investigators in other countries regarding the causes of infectious diseases. Then came the discovery of porcelain filters, filtrable viruses and the toxicity of bacterial filtrates, out of which grew the science of immunology. The authors acknowledge their debt in writing this historical outline to Bulloch's History of Bacteriology, which they say is the most reliable and valuable account of the history of bacteriology. The remainder of the book is more than a textbook of bacteriology. It has been the authors' purpose to develop the work into a manual of infectious diseases. The two purposes have been held in just balance in the same volume. In rewriting and revising there has been some material omitted that was uncertain and a great deal of new material added. The present plan of the authors has made this work more helpful and of great practical value.

Le barbiturisme aigu et les antidotismes gardenal: strychnine, coramine, alcool. (Recherches expérimentales). Par G. Carrière, professeur de clinique médicale à la Faculté de médecine de Lille, Claude Huriez, chef de clinique médicale à la Faculté de médecine de Lille, et P. Willoquet. Paper. Price, 30 francs. Pp. 164, with illustrations. Lille: Imp. A. Durant, 1934.

This little volume deals with the clinical and pathologic symptoms of barbiturate poisoning, such as coma, fever, blood changes and tissue lesions. It is demonstrated that the toxic effects of barbiturates are not restricted to the central nervous system but that the heart, liver and kidneys, as well as other structures, are affected. In addition, the treatment of this intoxication by means of strychnine, coramine and alcohol is discussed. The literary data are collected and supplemented by observations from experiments on twenty laboratory animals. It is pointed out that the antagonism between barbiturate and strychnine is rather incomplete and irregular and that in certain phases, as for instance in regard to the heart, there may be some synergistic action; that the antagonism with coramine, on the other hand, is quite complete, and the dangers of untoward results less imminent. The authors suggest the possibility of using intravenous injections of 30 per cent alcohol in the treatment of barbiturate poisoning. For the efficiency of this treatment, some experimental data and clinical evidence are submitted.

Medicolegal

Workmen's Compensation Acts: Disability Following Administration of Antityphoid Inoculation Compensable.

—The defendant company maintained in its mill a first aid station, with a trained nurse in charge. The nurse, among her other duties, administered antityphoid inoculations to employees. The plaintiff-employee in this case, Smith, suffered a paralysis of his left arm and serious and permanent impairment of his "shoulder and right side, abdomen, and hip," following the third injection of the "serum." He was denied compensation in proceedings brought under the workmen's compensation act of Louisiana and appealed to the court of appeals of Louisiana, second circuit.

Smith's right to compensation, said the court of appeals, depends on whether or not the disability following the third injection constituted an accidental injury that arose out of and in the course of his employment. The puncture of the skin with the hypodermic needle and the forcible injection into the system of the "serum" was an act of violence to the physical structure of the body. The act itself was contemplated but the results directly attributable to the act happened suddenly and were wholly unforeseen and unexpected. That the injection caused the disability was admitted, continued the court, but the medical testimony was in conflict as to whether the unfortunate results were attributable to an idiosyncrasy on the part of the employee or to injury to the musculospiral nerve. The court concluded, however, that there had been a destruction of the musculospiral nerve by the injection of the "serum" into the area of the nerve, causing direct injury and shock. This finding was based on the facts that the employee had felt a tingling sensation in his fingers within a few hours after the injection, because the paralysis developed within twelve hours thereafter, because of the absence of any rash or skin eruption, and because of the fact that no injurious effects followed the two previous injections.

The nurse in this case, said the court, was not employed by the company from any altruistic motives but because her presence and the services rendered by her were a direct benefit to the employer. Insurance rates were reduced thereby and loss of time from work by employees was minimized. The employee owed a duty to his employer to avail himself of the facilities offered to prevent illness and absence from work. A typhoid epidemic would have been disastrous to the industry. It was consequently in the interest of the employer to have administered to employees the antityphoid "serum." While the evidence shows, continued the court, that employees of the company were not ordered or required to take the inoculations at the mill, the wording of the notices that were posted may well have been interpreted by the average employee as such a requirement. The employee in this case testified that he understood that he was required to accept the treatment and that he was so told by the company physician. The court of appeals concluded, therefore, that the injury constituted an accidental injury arising out of and in the course of employment. Judgment was rendered accordingly for the employee. —*Smith v. Brown Paper Mill Co., Inc. (La.)*, 152 So. 700.

Evidence: Admissibility of Testimony Based in Part on Roentgenograms Neither in Evidence Nor Identified.

—In proceedings instituted under the Oklahoma workmen's compensation act, the employee called his attending physician, who testified that he had been unable to determine the nature and extent of the employee's injuries without roentgenograms and accordingly had sent him to another physician to have roentgenograms taken. The attending physician was not present when the roentgenograms were taken. The roentgenologist did not testify nor were the roentgenograms offered in evidence. The attending physician was permitted, over the objection of the employer, to testify as to the extent of the injuries, his testimony admittedly being based in part on examination of the employee and in part on examination of the roentgenograms. To review an award of compensation to the workman, the employer brought an action in the Supreme Court of Oklahoma.

The principle involved in this case, said the Supreme Court, is the same as the one that was involved in *Bartlesville Zinc Company v. Fisher*, 60 Okla. 139, 159 P. 476, wherein it was said:

The admission of x-ray plates in evidence rests fundamentally on the theory that they are the pictorial communication of a qualified witness who uses this method of conveying to the jury a reproduction of the object of which he is testifying, this being true, the x-ray plates must be made a part of some qualified witness' testimony and the witness should qualify himself by showing that the process is known to himself to give correct representations and that it is a true representation of such object.

The problem in the Bartlesville Zinc Company case, continued the court, was whether the roentgenograms were admissible without proper identification. The question here presented is whether medical testimony based on roentgenograms was admissible in evidence in the absence of a showing that the roentgenograms were authentic. Obviously, the value of the testimony of the attending physician depended on whether or not the roentgenograms on which the testimony was partly based were authentic. No evidence being introduced to establish the authenticity of the roentgenograms, the testimony of the attending physician should not have been admitted. The Supreme Court accordingly vacated the award of compensation to the employee and directed the industrial commission to retry the claim. —*Southwestern Cotton Oil Co. v. State Industrial Commission (Okla.)*, 29 P. (2d) 122.

Evidence: Opinion of Expert Based on Hypothetical Question Including Testimony of Other Witnesses.—The better practice, says the Court of Appeals of Maryland, is to incorporate in a hypothetical question all the facts on which an expert witness is asked to give an opinion. The hearing or reading of the testimony of other witnesses is accepted as an imperfect substitute for the formal hypothetical question in furnishing the data for inference by the expert witness. But it is clearly improper to admit an expert's conclusion based on the reading or hearing either of all or of a specified part of the testimony in the case if such whole or part is conflicting with respect to material facts. The reason is that, when there is a conflict of testimony on material facts, no conclusion can be reached by the expert witness until he first determines which of the facts in conflict are true, and in making that determination he must necessarily invade the province of the jury and pass on the credibility of witnesses and the weight of evidence. —*Quimby v. Grechawick (Md.)*, 171 A. 59.

COMING MEETINGS

- Academy of Physical Medicine, New York, Oct. 30-31. Dr. Arthur H. Ring, 163 Hillside Avenue, Arlington, Mass., Secretary.
- American Society of Tropical Medicine, San Antonio, Texas, November 14-16. Dr. Henry E. Meloney, Vanderbilt University School of Medicine, Nashville, Tenn., Secretary.
- Association of American Medical Colleges, Nashville, Tenn., Oct. 29-31. Dr. Fred C. Zapffe, 5 South Wabash Avenue, Chicago, Secretary.
- Central Association of Obstetricians and Gynecologists, New Orleans, Nov. 1-3. Dr. Ralph A. Reis, 104 South Michigan Boulevard, Chicago, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 2-3. Dr. Lawrence D. Thompson, 3720 Washington Boulevard, St. Louis, Secretary.
- Inter State Postgraduate Medical Association of North America, Philadelphia, November 5-9. Dr. W. B. Peck, 27 East Stephenson Street, Freeport, Ill., Managing Director.
- Omaha Mid West Clinical Society, Omaha, Oct. 29-Nov. 2. Dr. Joseph D. McCarthy, 107 South 17th Street, Omaha, Secretary.
- Pacific Coast Society of Obstetrics and Gynecology, Oakland and Del Monte, Calif., November 21-23. Dr. Clarence A. De Puv, 230 Grand Avenue, Oakland, Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 14-16. Dr. Julio R. Kolenson, Box 3403, Santurce, Secretary.
- Radiological Society of North America, Memphis, Tenn., December 3-7. Dr. Donald S. Childs, 607 Medical Arts Building, Syracuse, N. Y., Secretary.
- Southern Medical Association, San Antonio, Texas, November 13-16. Mr. C. P. Loran, Empire Building, Birmingham, Ala., Secretary.
- Southern Surgical Association, Sea Island, Ga., Dec. 11-13. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
- Western Surgical Association, St. Louis, December 7-8. Dr. Albert H. Montgomery, 122 South Michigan Boulevard, Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

- Prolapse of Female Urethra. J. K. Ormond, Detroit.—p. 458.

Time of Human Ovulation.—Kurzrok and his associates observed the daily excretion of the follicle stimulating factor of the anterior pituitary-like principle in ten young women over extended periods of time. Sudden excretion of this hormone occurred at about the middle of the menstrual cycle and had a definite tendency to recur at about the same time in the following cycle. This sudden secretion of the principle from the anterior pituitary is considered to be the stimulus to the ovaries to induce ovulation. Evidence is given in support of the view that ovulation follows the excretion of the principle in about twenty-four hours. It is believed that ovulation cannot occur without this stimulus. The presence of this substance is not, however, evidence that ovulation has occurred. The time of ovulation as suggested by this method is in complete agreement with the results of all other methods used in the study of this problem. The greatest incidence of the excretion of the principle was between the tenth and thirteenth days and hence the greatest incidence of ovulation was between the eleventh and fourteenth days. One case suggests the possibility of menstruation without ovulation and another of ovulation without previous menstruation. Two of the patients thus studied who became pregnant while under observation show the early appearance of a positive Aschheim-Zondek test; on

the twenty-fifth and twenty-seventh days from the onset of the last menstrual period, or two days before and one day after the expected onset of the next menstruation. The sudden conversion from a positive Aschheim-Zondek test to a positive follicle stimulating factor of the anterior pituitary-like principle reaction at the end of pregnancy is suggestive of a multiplicity of the gonadotropic hormones from the anterior pituitary.

Treatment of Uterine Hemorrhages with Radium and Roentgen Rays.—Among 433 cases of uterine hemorrhages due to benign causes and treated by radiation, Schmitz observed that about one fourth of the cases presented myomas, the youngest patient being 27 and the oldest 68. The greatest frequency is between 36 and 50 years of age. The radium dose that assures invariably complete amenorrhea is about 1,800 mg. element hours. When this dose was used, repetition of treatment was never necessary. If roentgen rays are used, the dose of 450 roentgens should be applied, through two fields at the seat of the ovaries. Diagnostic curettage should precede application of radiation in all cases. If presumptive signs of a malignant condition are present and microscopic diagnosis does not corroborate the clinical diagnosis, massive irradiations should be employed as recommended for radiation treatment of uterine carcinomas. The good end results of irradiation in myomas of the uterus were 90.14 per cent. The mortality in myomas was three. One patient died from a septic peritonitis, following dilation, curettage and radium insertion, and two cases showed malignant changes, one and three years afterward respectively, so that the entire mortality in the myomas was 2.48 per cent. Malignant manifestations after irradiation were seen in less than 1 per cent of the 433 cases. In the bleeding uterus, the good end results from radiation were 98.66 per cent. Radiation therapy is the method of choice in well selected, uncomplicated cases of uterine hemorrhages due to benign causes.

- *Studies on Crystalline Lens: Role of Tetany in Parathyroid Cataract. Everett I. Evans, Chicago.—p. 840.

Crystalline Lens.—Evans thyroparathyroidectomized young dogs kept on a special bread-sour milk-liver diet for a month after weaning. Tetany was not seen to occur in any of the young dogs so treated. Examination of the lenses of these animals indicated that there was a characteristic change in the lenses of the young parathyroidectomized dog similar to that described by Goldmann. The chief difference between Goldmann's experiments and the author's is that Goldmann noted no lenticular change if tetany was not allowed to occur. In these dogs, characteristic lens changes occurred although no tetany was seen. So far as the author can determine, these experiments offer conclusive evidence that the tetany which usually occurs during a state of parathyroid deficiency plays no part in the development of the cataract. The toxin theory of parathyroid deficiency presented by Luckhardt and by Dragstedt is not popular, because of the seemingly overwhelming evidence in favor of the calcium theory. Nevertheless, the author believes that in the search for the cause of parathyroid and senile cataract one should pay more attention to the possible rôle of toxins. It is difficult to understand how glutathione could have disappeared partially from these cataractous lenses unless toxins do play a part in parathyroid deficiency.

Influence of Calcium and Phosphorus on Healing of Fractures.—Haldeman and Moore used monocalcium, tricalcium and dicalcium phosphate and calcium glycerophosphate in determining the effect of a local excess of calcium and phosphorus in the healing of fractures of the radii in seventeen rabbits. Healing was delayed in five and uninfluenced in seven; two rabbits died in the first week after operation, and in three, in which tricalcium phosphate was added, the healing was delayed on both sides, although complete union eventually resulted on the treated side, while the control defects went on to typical nonunion. The reason for this delay is not apparent. However, the conclusion seems justified that in certain cases of delayed union tricalcium phosphate is an aid to union. None of the calcium and phosphorus compounds used in excess seemed capable of accelerating the normal rate of healing. In this respect the results fail to follow the well recognized chemical law that increasing the concentration of the reacting substances speeds up the reaction. Because of this fact, it is probable that the process of ossification is more than the purely chemical equation which certain authors describe.

Thoracogenic Scoliosis.—Bisgard presents a study of the influence on the spinal column of thoracic disease in 518 cases and of the surgical operative treatment of thoracic disease in 336 cases. While lateral deviations of the thoracic spine had developed in a large proportion of the cases in both groups, in only eleven cases were the deviations great enough to give rise to a deformity of major clinical importance. Deforming curvatures occurred in only a few cases with extensive chronic pleuritis and in an occasional case in which successful treatment necessitated an extensive Schede thoracoplasty or lobectomy. These deformities occurred only in children and young adults. Most pleural scolioses may be prevented by the early cure of the pleural disease and by constant maintenance of correction or overcorrection of the spine by postural wedging. Also, many instances of thoracoplasty scolioses may be prevented by constantly wedging the spine straight until it becomes fixed. For the control and treatment of certain severe and

progressive curvatures, internal fixation by fusion of the vertebral column is recommended. Every patient less than 20 years of age who has had chronic infection of the pleural cavity or has been treated by extensive thoracoplastic operations should be observed frequently for at least a year, and, if the curvature shows a tendency to progress despite conservative treatment, the spine should be fused to prevent the development of a severe deformity.

- Prevention of Puerperal Infection. L. L. Dozier, Tallahassee.—p. 106.

Perineorrhaphy.—Edwards, in repairing the lacerated perineum, has the upper part of the vagina well packed with gauze and the lower part of the vagina and the perineum prepared by the use of an antiseptic solution. An incision is made on each side of the laceration into the mucocutaneous border, extending outward to a point of election. A flap of the vaginal mucosa is dissected, with avoidance of any buttonholing, above the point where the levator ani fibers first meet in the recto-vaginal septum. The vaginal flap is not only held at its edge by Allis clamps, so as to inflict little contusion, but is steadied by the fingers of the hand holding the clamp and a thin flap is attempted by the use of scissors and gauze on the fingers of the right or left hand. The muscular bands are picked up, preferably with the fascia, and brought together in firm approximation. The tenacula grasp these muscles or fascial edges at the points of election and number 2 chromic gut is passed deeply into them and a figure of eight suture is made after the technic of Holden. The suture does not embrace the skin. One interrupted or figure of eight suture is placed high above the point of the usual appearance of a rectocele. A continuous chromic suture is passed back and forth from one side to the other; deep bites of the perineal tissue are taken; it is drawn firmly together, and a thick heavy new perineum is built up. Usually a portion of the redundant vaginal flap is excised and continuous number 1 chromic gut is placed in the mucosa beginning at the upper angle, every second bite taking up a portion of the newly acquired perineal body so as to prevent any dead space, and is tied at the former mucocutaneous margin. One silkworm gut suture is inserted deeply into the face of the perineum, one-third inch from the edge of the incision, entirely surrounding the mass of tissue held by chromic gut sutures and coming out on the opposite side again one-third inch from the edge, and a single knot of four or five turns, placing a bar across the line of suture, is tied judiciously to avoid enough pressure to cut into the skin of the perineum. Two, three or four metal clips approximate the skin. The clips may be removed in from five to seven days, while the silkworm gut may remain from seven to ten days.

Cow's Horn for Fixation of Fractures.—Fowler employed cow's horn in nine patients who required open reduction with fixation. Prompt abundant callus and bony union occurred without complications. An incision was made somewhat to the side of the fracture selected for the drill hole. A good sized hole was drilled carefully through the cortex into the medullary channel at a distance of from 1 to 3 inches from the fracture. The hole was then reamed obliquely toward the fracture so that the horn could be passed or gently driven through the oblique hole along the medullary canal well beyond the fracture. Usually the medullary spaces require some reaming before the horn can be passed into the medullary canal and well beyond the break. The distance necessary will vary from one to several inches, depending on the size and length of the bone involved. In the thirty cases, including the author's, in which horn has been used for internal fixation of fractures, it seems to have been an ideal material for strength, elasticity, absorbability and ease of sterilization. In addition it was found to be nonirritating, mildly bactericidal and stimulating to callus growth. The author believes that his simplified technic diminishes trauma and shock.

Comparative Effects of Intravenous Administration of Acetylcholine and Acetyl-Beta-Methylcholine.—Weiss and Ellis state that the general and the cardiovascular responses in normal human subjects to the continuous intravenous infusion of acetylcholine and acetyl-beta-methylcholine are similar, but that the latter drug is approximately 200 times as potent as the former. Both compounds can be infused at a rate producing definite symptoms for prolonged periods without evidence of cumulative action. The velocity of the blood flow remains essentially unchanged during the intravenous administration of varying amounts of each substance sufficient to produce effects varying from minimal to marked. These observations indicate that the cardiac output can be measured with the acetylene method under the conditions described.

Neurocirculatory Instability.—Herrick applies the designation of neurocirculatory instability to a heterogeneous group of organically normal people presenting diversified skin conditions: neurodermatitis, dyshidrosis, urticaria and pruritus of the anus and vulva, that is, diverse skin conditions, the common element of sympathetic nervous system maladjustment creating excessive pruritus. These people are of the type who exhaust the reserves of nervous energy and show this fatigue. In such patients local treatment is only palliative, and permanent relief is obtained by aiding each person to solve his own situation by frankly understanding the cause and the factors involved, and, in addition to local therapy, presenting for his acceptance a logical program of daily relaxation. This is not easy, but usually patients of this group are intelligent and have passed from doctor to doctor with much futile local therapy, and they do respect a thoughtful analysis of their problems. Many such patients have no demonstrable pathologic condition

but have lived for years under exhausting nervous tension and some time in their career the weakest link has given way. Neurocirculatory instability is a functional diagnosis.

Primary Tuberculous Infection.—Stewart's concept relative to the evolution of tuberculosis in the human lung from the first infective phase to the final stage of far advanced phthisis implies that the first infection makes possible rather than prevents the development of the adult type of tuberculosis. When other serious reinfective forms of the disease are considered, these conditions which develop as the result of the discharge of bacilli from pre-existing primary foci of disease, are seen to be caused often by the dissemination of direct descendants of the initial infective dose of tubercle bacilli that entered the body. There is no form of tuberculosis to which man is susceptible that is prevented by the first invasion of the tissues by tubercle bacilli. In fact, the primary infection is the first step along the path which leads too often to the development of all the serious reinfective varieties of tuberculosis that menace the human race. As a result of several years' study the Lymanhurst staff considers a negative tuberculin reaction superior to a positive one and looks on the nonallergic, uncontaminated person as occupying a more advantageous position than is possessed by infected patients so far as future experiences with tubercle bacilli are concerned. The prediction is ventured that in the near future an initial infection with tubercle bacilli will be generally accepted as a hazardous liability rather than a protective asset, and a deeper appreciation will arise relative to the soundness and value of campaigns fostered by national, state and local tuberculosis associations directed toward the prevention and control of tuberculosis.

The Subarachnoid Space During Procaine Hydrochloride Anesthesia.—Velrs believes that the use of the lateral recumbent and flexed posture is superior to the dorsal decubitus in fixing nerves with procaine hydrochloride, because in this posture the dural sac has no obstructing curvatures, while in the latter the dural sac has varying lumbosacral curvatures. The fixation of nerves and diffusion by procaine hydrochloride is so well controlled through the use of this method that it deserves a critical study and a continued usage. Deprocaminization by aspiration of the spinal fluid from the dural sac attenuates the subarachnoid concentration of the procaine and lessens the time of nerve block. The spinal fluid that is removed in deprocaminization of the dural sac permits procaine free fluid from above to attenuate further the remaining procaminized fluid. A study of the chemistry of anesthetic drugs in the spinal and cisternal fluid is necessary to establish their safety and to act as a control in establishing the proper methods of administration. A study of the lumbosacral curvatures will assist one in the control of nerve block in the use of dorsal decubitus.

Vitamin D in Hypervitaminosis D Rickets.—Ham and Lewis observed that young rats receiving daily large doses of vitamin D showed rachitic lesions in their long bones after three weeks. As the matrix which formed in the bones during the experiment was calcified poorly, it was concluded that the administration of large amounts of vitamin D inhibited the normal calcification process in bone. As osteoclasts did not form a prominent part in the histologic picture, the poor calcification of bone could not be attributed to them. The authors explain the phenomena observed in their experiment by the theory which considers that vitamin D acts by increasing in some way the attraction of the blood for calcium. The results are compatible with, although they do not support directly, the theory that vitamin D acts through the intermediary of the parathyroid mechanism to control a fraction of the serum calcium.

Influence of Injury in Genesis of Tumors of Gonads.—Willis carried out experiments on the testicles and ovaries of rats to determine by some form of traumatic or chemical stimulation whether it was possible to evoke teratomatous growth in gonadal tissue. He reasoned that if this was possible his experiments would provide evidence in favor of the view that teratomas are the products of some kind of parthenogenic or epibogonic proliferation of germ cells. The experiments on male rats consisted of injections into the testicles through a hypodermic needle. In female rats the ovaries were reached through a midline laparotomy. Oxidizing, reducing, coagulating and necrosing agents as well as simple mechanical trauma, the introduction of silica and the introduction of blood were employed. The animals were kept for periods ranging from twenty-five to thirty-five weeks thereafter. The changes observed in the damaged organs were those of necrosis and its sequelae; no tumors appeared. The experiments afford no evidence that local injury is capable of evoking neoplasia in gonadal tissue. The result obtained served to strengthen the suspicion that injury and inflammatory processes play no more than a coincidental part in the histories of patients with testicular or ovarian tumors.

*Facial Paralysis "a Frigore," Cured by Decompression: Two Cases. P. G. H. Sander.—p. 503.

Facial Paralysis Cured by Decompression.—Sander points out that many different clinical conditions may cause compression of the facial nerve in the fallopian canal. Congestion of the periosteum or neurilemma, hemorrhage, inflammatory exudation within or without its sheath, production of fibrous tissue or hypertrophy of bone—all would act as a compression factor. An exceptional anatomic position of the nerve in a narrow, rigid and comparatively long canal and attachments of its sheath to the periosteum make the adjustment of the nerve to this condition difficult, impede their elimination or absorption and tend to maintain the localization of the compression factors. Every case of spontaneous Bell's palsy of "unknown origin" that does not show any tendency to a definite improvement within a few days after its onset should pass into the realm of surgery, regardless of its relation to the severity of the condition of the middle ear. The earlier the decompression is done, the better are the prospects of the operation. Both the complete and definite paralysis of the facial nerve and the incomplete recovery, with subsequent contractures, abnormal twitching and sympathetic movements are most distressing conditions, and any attempt to prevent them by a decompression operation should be fully justified. There is a striking analogy between this question and the problem of glaucoma. The symptom complex of glaucoma is probably a deeper mystery than Bell's palsy. But the high value of hypotonizing operations aiming at the relief of the symptom of intra-ocular pressure on the optic nervous system is now generally recognized. The operations for glaucoma are now a routine procedure in the hands of every ophthalmic surgeon, to the great benefit of many thousands of patients. The same principle induced Worms to devise his operation for decompression of the optic nerve in the optic canal to relieve the condition of optic neuritis, regardless of its etiology. The author presents two cases of facial paralysis cured by decompression.

*Quantity of Circulating Blood and Its Behavior in Chronic Cardiac Insufficiency. A. Landau, Mlle. M. Markson, T. Goliborska and I. Lewicki.—p. 453.

Basal Metabolism and Specific Dynamic Action in Cardiac and Hyperthyroid Patients. A. Berland and T. Donskova.—p. 510.

Quantity of Blood and Cardiac Insufficiency.—Landau and his collaborators used the method of Keith, Geraghty and Rowntree with the technical modifications of Seyderhelm and Lampe for determining the quantity of circulating blood. In twenty-eight cases of compensated but disordered circulation it was determined that myocardial degeneration and arterial hypertension were accompanied by a normal circulating blood value, mitral lesions and pulmonary emphysema with an increased volume. In pulmonary emphysema, this increased volume carried with it an increased proportion of erythrocytes. Albuminuria in hypertension, progressive endocarditis or a syphilitic etiology lower the polycythemia. The studies of the amount of circulating blood in fifty-two patients with decompensation were brought into relation with the minimum body weight after disappearance of the edema. The average amount of circulating blood in these cases was 118 cc. per kilogram of body weight, that of the plasma 53 cc. and the hematocrit index therefore (ratio of erythrocytes to total blood) 53 per cent. Those cases of myocardial insufficiency with edema and circulatory slackening are characterized by increased volume produced by the plasma and especially the erythrocytes. Greater polycythemia occurs following insufficiency of the right side of the heart due to pulmonary edema than in myocardial degeneration or in mitral or aortic lesions. In seventeen patients the quantity of circulating blood was determined several times in order to study the influence of compensation and loss of edema. After compensation the quantity of circulating blood diminishes, but it differs in individuals. The average quantity was 122 cc. per kilogram of body weight and 104 cc. after disappearance of edema. The authors could not find, however, any relationship between the quantity of circulating blood and basal metabolism.

Toxic Factor of Placenta Praevia.—In placenta praevia, Nubiola believes that there is a toxic factor derived from the placenta and affecting the fetus and mother. Following an anatomic study of the placenta of three cases, he believes that the toxic factor is produced by the liquefying of the placental cells and that this is reflected in the blood of the mother and especially of the fetus. The mechanism is due to an alteration of the villi, which become swollen and ruptured and end by dissolution of their cellular elements. The deposits of fibrin and other lesions previously studied are the results of placentalolysis. These placental changes are not peculiar to placenta praevia but are similar to those observed in uteroplacental apoplexy and nephritic placentas. Analogous disorders are observed in red and white infarcts and even in apparently normal placentas but are limited in these to small regions and are of low degree. Confirmation of these results may have a clinical interest as an indication for early intervention.

Devitalization of Periosteum in Thoracoplasty. R. Mariani.—p. 402.

Leukocytometric Formula in Typhoid.—Parini found that the diameters of neutrophils in normal healthy persons vary from 10.85 to 15.5 microns. Those of the lymphocytes run from 6.2 to 12.4 microns. There is a prevalence of larger forms in women. Of nineteen patients presenting typhoid,

seventeen showed a deviation to the right of the leukocytometric formula during the incipient stage of the disease. The deviation became marked during the second stage but began to diminish during the period of defervescence. Two cases evincing a deviation to the left resulted in death. The author states that macrocytic leukocytosis is due to a lack of diminutive mitoses of Dustin, whereas microcytic leukocytosis may be attributed to an excess of these mitoses.

Cerebral Disturbances During Childhood.—Rupilius's paper is based on the clinical histories of all children with disorders of the central nervous system who were observed in the children's clinic in Graz in the last fifteen years. He divides the material into nine groups: acute encephalitis, cerebral paralysis, weakmindedness without paralysis, hydrocephalus, microcephalus, deaf-mutism, cerebral syphilis, cerebral tumors and other cerebral lesions. He points out that the incidence of acute encephalitis seems to have increased in recent years, and that there was in nearly all groups a slight preponderance of boys. A differentiation according to age groups disclosed that the incidence of cerebral disturbances was highest in children less than 2 years old. The history revealed difficult delivery in a high percentage of cases. The incidence of premature births corresponded in most of the groups to the usual ratio of approximately 10 per cent. The incidence of disturbances in the intelligence was rather high, but imbecility was twice as frequent as idiocy. Paralytic symptoms were present in more than 50 per cent of the cases. Hydrocephalic and microcephalic deformities of the cranium were present not only in children in whom the disorder was diagnosed as such but also in some who had other disorders. In a large percentage of cases the cerebral disturbances were accompanied by epileptiform and other convulsive attacks. The cerebrospinal fluid was examined in more than half of the cases, but pathologic changes were observed in only 25 per cent of the examined cases. The highest incidence of pathologic cerebrospinal fluids was observed in the cases of acute encephalitis. Following a report of certain observations made in the course of necropsies, the author discusses the causes of the cerebral disturbances, showing the rather high incidence of an acute or a former encephalitis (27 per cent, or 150 out of 548 cases). Trauma sustained during birth was found responsible in only sixty-two cases, although the history revealed a difficult birth in 149 cases. A differentiation of the prenatal disturbances into those of endogenous and of exogenous origin did not succeed entirely.

Mode of Action of Roentgen Rays on Diseased Human Thyroid.—Sunder-Plassmann points out that there is no unanimity of opinion as to the mode of action of roentgen irradiation on the diseased thyroid. His observations of a large series of histologic studies of both irradiated Basedow thyroids and nonirradiated thyroids in the surgical clinic of the University of Münster led to the conclusion that no definite alterations are to be found in the parenchymal cells of the gland after irradiation. Definite changes, however, were observed in the interglandular vegetative nervous apparatus. These studies demonstrated an extraordinary richness of the peripheral sympathetic nervous supply of the thyroid. The sympathetic nerve fibers enter the gland together with the

branches of the recurring nerve and of the superior laryngeal nerve, and with the fibers that run in the walls of the blood vessels. Immediately on entering the gland these nonmedullated nervous elements form plexuses, which enter each parenchymal cell and there break up into a fine meshwork—the terminal nervous reticulum. This reticulum is so fine that in order to obtain a photomicrograph of it the greatest magnification under the oil immersion lens is required. The fibers of the reticulum never terminate but are seen to be continuous with the protoplasm of the neighboring cells, binding all the cells into one neuromuscular functional unit. These fibers continue in the walls of the capillaries and the walls of the larger blood vessels, the combination suggesting a “neurovascular regulating mechanism.” The same pathologic alterations were observed after irradiation in the terminal nervous reticulum in cases of simple colloidal or cystic goiter as in hyperthyroidism. The difference in the two is that in the latter the irritating impulse is of central nervous origin. This irritation alters the nature of the secretion and this in turn brings about the degenerative changes in the terminal reticulum. The sympathetic terminal reticulum may be intact in the early cases of thyrotoxicosis. It is therefore possible, in the author's opinion, to terminate a beginning hyperthyroidism by a timely cervical sympathectomy. Roentgen irradiation can accomplish the same result. That explains some of the successes with roentgen therapy. The effect of the rays in paralyzing the terminal sympathetic reticulum may bring about cessation of the morbid process. The roentgen rays affect these fibers because of certain pathologic alterations in the colloid of the neurofibrils. On the other hand, the well developed exophthalmic goiter presents an irreversible process, which can no longer be affected by irradiation. The timely irradiation of the hyperthyroid may be regarded as a “bloodless resection of the cervical sympathetic.” The author is of the opinion that irradiation may likewise influence beneficially the refractive residual symptoms after a resection, particularly the exophthalmos. He considers hyperthyroidism an irreversible process best cured by a subtotal resection of the gland.

Heterotopic Intestinal Mucosa in Stomach and Gastric Ulcer.—Clar examined the stomachs of fifteen fetuses from 6 to 9 months of age. The stomachs of all the fetuses up to the seventh month presented, on histologic studies, either single or grouped typical intestinal crypts. Of three full-term infants, heterotopic intestinal mucosa was found in only one stomach. Heterotopic intestinal mucosa was not found once in a study of twelve cadavers without a history of gastric disease, or in twenty-six stomach specimens resected for the cure of a duodenal ulcer. The observations of these heterotopic islands in diseased stomachs is a common experience. Thus, the author found it six times in ten stomachs resected for gastric ulcer, and once in three specimens resected because of pyloric ulcer. Gastritis was not present in any of the cases in which the author found heterotopic islands of intestinal mucosa. These islands were found by the author, as well as by other observers, to be located most frequently in the pyloric, the prepyloric and the lesser curvature regions. On the basis of his observations the author considers heterotopic intestinal mucosa in the stomach a congenital displacement and not of metaplastic origin. He admits the possibility of secondary epithelization of defects in the gastric mucosa by preexisting intestinal cells. The intestinal mucosa may be digested by gastric juices. The peptic action of the gastric juice may lead to an erosion of the displaced intestinal mucosa and the latter, in the presence of other predisposing factors, may develop into a chronic peptic ulcer. Stomachs containing islands of heterotopic intestinal mucosa are particularly predisposed to inflammatory and ulcerative processes.

Origin and Prevention of Thrombosis.—Havlicek makes an effort to consider synoptically the three probable causes of thrombus formation: the slowing of the blood current, the damage to the wall of the vessel and the chemical changes in the blood. The present views regarding the peripheral circulation fail to explain satisfactorily the velocity of the venous current. The author points out that there are numerous localizations in the peripheral circulation in which exists the possibility of shunting the arterial blood directly into the venous

circulation. The author refers to arteriovenous anastomoses. The anastomoses differ from both the arteries and the veins in their structure. The characteristic anatomic feature of these “short cut” vessels is that they are lined by what the author chooses to call “hydraulic” cells. The latter possess the property, when acted on by a number of autogenous as well as heterogenous substances, to swell and thus to shut the lumen of the vessel, or to empty and thus to open up the vessel. The effect of the opening of the arteriovenous anastomoses is to cause oxidation of the venous blood, to impart pulsation to veins and to accelerate the venous blood current. The chemical changes supposedly responsible for thrombus formation suggest the possibility of mixing of the peripheral venous blood with blood from the portal circulation. The portal system is not entirely separated from the peripheral venous system. There exist numerous anastomoses between the branches of the portal vein and those of the vena cava. Such an anastomosis exists between the inferior hemorrhoidal vein and the extensive pelvic plexuses that belong to the general circulation, the superior hemorrhoidal vein, a branch of the portal system. There also exist numerous anastomoses between the two systems at points of attachment of the intestine to the posterior abdominal wall. The author demonstrated these portal-caval anastomoses in cadavers by filling the two venous systems with a luminescent fluid and illuminating the latter with ultraviolet rays. The author further cites his studies that demonstrate the striking differences in the blood of the peripheral veins and that of the portal veins so far as the leukocyte count, the sedimentation rate of the red cells, the viscosity and the globulin fraction are concerned. A comparison of the ability to resist sclerosing effects by the arteries, the peripheral veins and the mesenteric veins reveals that the vessels which drain the toxic substances of the intestine, the vessels of the portal system, are most resistant. It is the author's opinion that the vomiting, retching, coughing and meteorism occurring after an operation may cause the passage of the blood from the portal vein into the branches of the vena cava by way of the portal-caval anastomoses. The blood laden with noxious substances may thus reach the femoral and even the saphenous vein. The mixing of the two kinds of blood, one of which, in addition to a difference in physical and chemical characteristics, contains toxic substances, leads to agglutination, to changes in the wall of the vessel and thus to formation of a thrombus. In the last five years the author has adopted the method of exposing the operative field to ultraviolet rays and has not had a single case of thrombosis or embolism. He theorizes that the effect of ultraviolet rays on tissues is to release histamine. The latter has a stimulating effect on the arteriovenous anastomoses, which in turn accelerates the venous current and prevents venous stasis. The author believes that, by exposing the intestine to ultraviolet rays in cases of acute peritonitis, splanchnic stasis can be prevented.

Roentgen Treatment of Hay Fever.—Schreus says that roentgen therapy has effected desensitization in various allergic disturbances, such as allergic bronchial asthma and eczema. His method of roentgen treatment of hay fever consists in two or three applications of 15 or 20 per cent of the unit skin dose to the nose. The fields are 6 by 8 cm., and the rays are filtered through 0.5 mm. of copper. Follow up of patients who received this treatment from 1930 to 1933 revealed that the treatment was more or less effective in twenty-two of thirty-five. The other thirteen patients were not influenced. The author thinks that a combination of the injection of pollen

extracts with roentgen irradiation may produce more favorable effects, in that the general desensitizing effect of the injections is promoted by the local action of the roentgen rays. He suggests that in this manner it might prove possible to shorten the rather long and expensive injection treatment. The author does not expect much from a combination with other local treatments but thinks that calcium and dietary treatments may be helpful adjuvants.

Protein Economy and "Dextrose Effect" in Oxygen Deficiency.—Elias gives a summary report of studies on the metabolism under negative pressure. He gave especial attention to the behavior of protein metabolism during oxygen deficiency and to its modification by sugar. Animals were kept for several days under negative pressure, while controls were kept under normal atmospheric pressure and were left to starve and suffer from thirst. Compared to the latter group of animals, those kept in oxygen deficiency showed great loss of water and of protein, while the loss in fat and glycogen was comparatively slight. Further tests proved that the liver of these animals showed a relative increase in nitrogen, and since the peripheral portions of the animals had lost nitrogen and there had been no food intake, nitrogen must have gone from the periphery to the liver. Studies on the blood revealed a decided inspissation and an albuminemia, and both these factors must result in an increase of the oncotic pressure. Certain observations on epileptic persons and the fact that nervous symptoms appear in persons at high altitudes led to studies on the galvanic irritability of animals that had been under negative pressure for three days, and a considerable increase was found. Since all these tests were made on animals that received neither water nor food, a new series of tests was made, one group of animals receiving water, another fat, a third protein and a fourth sugar. It was observed that in case of administration of water the nitrogen rest in the blood (indicator of the protein changes) increased considerably, although not quite as much as formerly. Administration of fat reduced the nitrogen rest only slightly more than did the water intake, while protein increased it considerably. The administration of dextrose, however, effected only a slight increase in the nitrogen rest and thus approached in this respect the normal protein metabolism. Administration of dextrose to animals kept under negative pressure produced nearly a normalization of the red and white blood pictures. Thus not only the disturbances in the water and protein exchanges had to be cleared up but also this so-called dextrose effect. The author relates further studies on the changes in the water and protein exchanges under oxygen deficiency and stresses that the most interesting factor is the modification of these changes by dextrose. In summarizing the effects of the administration of dextrose he points out that (1) it reduces the increased nitrogen rest and brings the pathologic protein exchange closer to the normal status; (2) it prevents the inspissation of the blood; (3) it decreases the galvanic irritability, which is increased during oxygen deficiency, and (4) it prevents to a large extent the changes in the blood picture. If the dextrose administration influences such widely different processes, its point of attack must be at a superordinated center. The author considers it possible that abnormal protein metabolism may be the common cause of all other disturbances and that dextrose regulates the protein exchange and thus counteracts simultaneously all the secondary phenomena. He admits, however, that this is only a hypothesis, which might eventually be replaced by a better one.

Alcohol and Liver Function.—Bauer and Wozasek found that in normal persons alcohol effects a considerable impairment in the assimilation of galactose. This action of alcohol can be graduated in that greater doses of alcohol effect a more severe galactosuria. In patients with liver disease, particularly in those with acute damage to the parenchyma, the effect of alcohol is paradoxical. The galactosuria caused by parenchymal impairment is not further increased by the administration of alcohol. On the contrary, a larger dose of alcohol produces a reduction in the elimination of galactose. This paradoxical behavior of the diseased liver in response to a substance like alcohol that ordinarily injures the liver is inexplicable. Considering the complex action of alcohol on parenchymal and nerve cells and on the vascular system, an explanation is as yet impossible.

Prophylaxis of Diphtheria.—Pöeh and Leach show that it is possible to conduct a campaign against diphtheria in rural districts and give consideration to all legally required control measures. Their studies were made on 4,879 children, between 2 and 8 years of age. Of this number 1,746 (or 56 per cent of those with a positive Schick test) were given three subcutaneous injections of toxoid. The doses were 0.5, 1 and 1.5 cc, and the intervals between injections ten or fourteen days. The toxoid never caused undesirable complications. Repeated Schick tests revealed that 12 per cent remained positive in spite of vaccination. The morbidity ratio of the vaccinated and non-vaccinated was 4:9, which proves that the toxin protection had not sufficiently developed. In one locality, in which the diphtheria epidemic was especially severe, 19 per cent of the vaccinated children and 39 per cent of those who had not been vaccinated contracted the disease. Moreover, the fact that not one of the vaccinated children had a severe form of diphtheria and that all fatalities occurred among the nonvaccinated is a further proof of the protective action of vaccination against diphtheria.

Hyperthermic Factor in Malarial Therapy of Dementia Paralytica.—Pogibko treated fifty patients suffering from dementia paralytica with malarial therapy. He obtained a primary and a secondary remission in 50 per cent of the cases, and a third remission in 28 per cent; 12 per cent were not influenced by the treatment and 10 per cent of the patients died. The greatest number of favorable remissions was obtained in the early stage of the disease (neurasthenic), and next in the exalted stage. The earlier treatment is begun, the higher is the percentage of remissions. The percentage of first- and second remissions in cases of from one to two months duration amounted to 72.8 per cent. These figures emphasize the desirability of early malarial therapy. The number of first and second remissions increases with the increase in the total number of hours of febrile temperature. The author likewise noted that the quality of temperature exerted a definite influence on the permanence of the results. Better remissions were obtained with an increase in the number of hours of temperature above 102.2 F. This was particularly true in the exalted group. The author is of the opinion that the hyperthermic factor is not alone responsible for the curative effects. In all probability there exist biologic factors in malaria. In the evaluation of the malarial therapy the number of febrile hours and the height of temperature are probably as important as the number of malarial attacks. The author computed on the basis of his material that the best results are obtained from a total number of febrile hours ranging from a minimum of 101 hours to 200, and that of the total number of febrile hours there should be from 51 to 100 hours above 102.2 F.

VALUE OF CALMETTE VACCINATION IN PREVENTION OF TUBERCU- LOSIS IN CHILDHOOD

ARVID WALLGREN, M.D.

GOTHENBURG, SWEDEN

In a critical survey of the reports on experimental vaccination on human beings I attempted in 1926 to draw up some principles for carrying out an anti-tuberculous vaccination. Tentatively I began working along these lines and as the experiment seemed to turn out well I have continued along the path struck. In 1928 I published in *THE JOURNAL* a preliminary account of my experiments,¹ and I now submit the results achieved up to the present.

The history of the production of the BCG vaccine is no doubt well known and I shall therefore content myself . . . that the vaccine is composed of an . . . strain of bovine tubercle bacilli, which by means of certain methods of cultivation has been made very nearly avirulent. To be approved, a vaccine of this kind should fulfil at least these two primary conditions: It should be free from any element of danger and it should be effective.

With regard to the first of these requirements I dare say that the majority of my auditors are well aware that opinions have differed rather widely. The charge has been made that the vaccine or some bacillary agents contained therein are virulent, and in proof of its danger the report of one unfavorable instance after another has been published. A careful and critical study of the available literature shows, however, that up to the present not a single one of the million children who have been vaccinated has suffered any evident harm from a correctly prepared and correctly employed vaccine. From this it would seem that one is justified in drawing the conclusion that under these conditions the vaccine is safe. I shall report later my own experience with regard to the harmlessness of the vaccine.

Opinions differ also concerning the efficacy of the vaccine. This is chiefly due to the difficulty of procuring control material for comparison. On this account the vaccination experiments carried out in France on such a gigantic scale have not been considered conclusive. That the vaccine does produce a certain amount of immunity in animals has, on the other hand, been definitely proved. When the vaccine is injected in suitable doses into certain animals, they become sensitized to tuberculin after the lapse of a certain time and are less susceptible to mild virulent reinfections than untreated control animals.

That even human beings acquire a certain increased resistance by means of a BCG vaccination resulting in tuberculin sensitization has been proved by Heimbeck's experiments on tuberculin negative probationary nurses at Oslo. Out of 136 nurses vaccinated, only three became ill after having attended tuberculous patients in the course of their duty, while of the thirty-four unvaccinated probationers, unaffected when they began their duty, not less than fourteen fell ill with tuberculous disease. This is the only experiment in vaccination performed on human beings so far in which an adequate control material has permitted a comparison between vaccinated and unvaccinated subjects. This experiment furnishes definite evidence that a BCG vaccination is capable of producing a certain degree of immunity even in human beings. The report given before this section last year by Park, Kereszturi and Mishulow² of the vaccination experiments carried out in New York also lends support to this view.

A virulent primary infection does not produce more than a very relative immunization, and since the avirulent BCG infection is surely less intensely immunizing than a virulent infection it cannot of course be expected that a vaccination will afford absolute protection. That would be placing too great a demand on the vaccine. It should also be clearly understood that a BCG vaccination cannot protect the individual from secondary or tertiary tuberculous diseases any more than a natural tuberculous infection can do so. At best it can only prevent the severest forms of primary tuberculosis.

In my vaccination experiments I have followed these two principles: First, only healthy children in danger of being infected have been vaccinated; second, the vaccinated children have been protected from virulent infection until they have become sensitized to tuberculin by the inoculation.

From what has just been said it is evident that as yet there is very little information and experience relating to the usefulness of an antituberculous vaccination in children. The extent to which it protects the child against the dangers of a virulent infection is not known, nor is there any knowledge of the duration of such a protection. Under these circumstances the wisest plan seems to be to confine vaccination to those children who may be suspected of being exposed to the risk of infection in the near future. This is the case with all children of tuberculous parents.

In order to obtain any benefit from being vaccinated, the child must be free from tuberculosis. An infected child has already by means of the natural infection acquired that immunity which a vaccination is intended to produce. Hence, vaccinating an already infected child is absolutely superfluous. But it is not only

superfluous; it should also be avoided. In order to estimate the value of the vaccination it is imperative that accurate information be acquired with regard to the child's state of health, especially if it is infected before being vaccinated.

New-born infants can as a matter of fact always be regarded as free from tuberculosis. On the other hand, if the child has lived for some time in a tuberculous

surrounding the case is quite different. In such cases tuberculin tests will show whether or not the child has escaped infection. This can be determined only when the child has been separated from the source of infection for six or seven weeks. A negative tuberculin test after this period of quarantine will show that the child has not been infected. New-born infants and nonexposed children may therefore be vaccinated at once, but children who have been exposed to possible infection should be vaccinated provided they have shown themselves to be tuberculin negative after a lapse of from six to seven weeks from the date of their last exposure.

Calmette and his coworkers were of the opinion that vaccination with BCG produced a relative immunity without causing any tuberculin sensitivity. Now it is known that tuberculin sensitivity occurs just as well after a successful BCG vaccination as after a virulent infection. The only difference is that it is ever so much weaker and is possible of demonstration only by means of large doses of tuberculin. It is generally assumed that if immunity is acquired at all by vaccination it is present in those children who have become sensitized to tuberculin. Whether the immunity is already present before the tuberculin test has become positive is as yet unknown. When it comes to the question of deciding when a vaccinated child may be permitted to return to its tuberculous home it would

TABLE 2.—*Total Number of Children Vaccinated*

be safest at all events to assume that the child has acquired this immunity only when it has become tuberculin positive. It is on this principle that we have acted in the experiments made at Gothenburg.

Under such circumstances it is a matter of great practical importance to determine when the sensitivity to tuberculin sets in after vaccination. Calmette was of the opinion that immunity does not occur until after a month's time and therefore recommended that the vaccinated child be isolated for this period. From data to be submitted later it will be seen that it is absolutely

impossible in each separate case to determine in advance an exact period of one month's isolation. This is especially the case when employing the peroral vaccination recommended by Calmette. In this method the sensitivity to tuberculin occurs very late, usually not before the lapse of some months, sometimes not before six months or later, sometimes not at all. Sensitization is therefore a very irregular phenomenon, a fact which does not occasion surprise when one takes into consideration that the peroral method of vaccination implies such enormous variations in the size of the actually resorbed dose of vaccine.

For this reason it has been considered more appropriate to employ a technic of vaccination in which the effective dose can be determined in advance. This can be done by injecting the vaccine. In subcutaneous inoculations there frequently arise rather large and disagreeable abscesses. Of the various parenteral methods of vaccination my associates and I have therefore chosen the intracutaneous, thus ensuring that any eventual liquefaction of the focus of inoculation will be as small and superficial as possible. When an appropriate dose of vaccine is administered there never arise any unpleasant local reactions in intradermal vaccination. The focus of inoculation, which is hardly ever larger than a pea, undergoes only a slight liquefaction and heals entirely in the course of a few weeks.

The interval between the vaccination and the onset of the tuberculin sensitivity varies also in cases in which the vaccine is administered intradermally, but by

TABLE 3.—*Age of Exposed Children When Vaccinated*

no means so widely as in peroral vaccination. The sensitivity to tuberculin occurs, too, in a more reliable and fairly constant manner. The larger the dose of vaccine the quicker does allergy occur as a rule. With a vaccine dose of from 0.5 to 1 mg., tuberculin sensitivity is obtained after from one to three weeks (table 1), with a dose of 0.25 mg. after four weeks, with 0.1 mg. after six weeks and with the dose of 0.05 mg., which is used at present, after about seven weeks. On reference to the table it will be seen that even with exactly the same dose of vaccine there are very great variations, ranging from four to thirteen weeks with a dose of 0.05 mg. of BCG. These variations are due to individual constitutional factors, for the variations are equally great even if precisely the same preparation of vaccine is used, the same dose, the same method of application and in children of the same age.

From what has been said it is therefore evident that there is no possibility of determining beforehand when a child will be immune after being vaccinated. Judging from the conditions of tuberculin sensitivity, the acquisition of a state of immunity takes an unequal length of time in different cases. As a rule it occurs in about seven weeks, but occasionally it takes a considerably longer time. Indeed, in some cases the child is so insensitive to the vaccine that it does not react, either locally or by means of tuberculin allergy, even after a period of many months. In such cases the injections have been repeated, sometimes with increasing doses, until the child has finally reacted.

As already pointed out, we have not considered the child vaccinated until it has reacted to tuberculin. Until that occurs the child is not permitted to be exposed to any risk of infection. To ensure this the children during the period of vaccination have been isolated in an institution or in a private home. All children have been subjected to such a tuberculin control after vaccination.

In Gothenburg, a seaport town with a population of 250,000, since 1928, every child considered by the municipal dispensary to be in danger of infection has been vaccinated. This dispensary is thoroughly informed of practically every family any member of which has an open pulmonary tuberculosis. With only a few solitary exceptions it has always been possible to induce the parents to consent to the vaccination of the uninfected children at home. When the parents have been informed of the danger threatening the child at home and that for the sake of diminishing this danger they must either separate the child from the tuberculous member of the family or have the child vaccinated, they have of course chosen the latter alternative. In my opinion, the work of tuberculous vaccination in a community should be managed in this

Thus, altogether, only seven of the 355 inoculated children have died (table 2). Although this small number of deaths is in itself sufficient proof that the vaccination does not constitute any serious danger to the children, the following particulars are still more instructive: Out of 117 children who were vaccinated

way by the tuberculosis dispensary and should preferably be entrusted to a single person so that he will be in a position to supervise the whole work and to control the effect of the inoculations of the vaccine and the health of the vaccinated infants

Up to the end of December 1933 the number of children vaccinated amounted to 355. For various reasons, among others the death of the source of infection, 123 of these children had not yet been exposed to tuberculous infection after vaccination. Three of these 123 children have died and all three of them have been examined post mortem. The cause of death was congenital malformation of the heart with bronchopneumonia in one case, pertussis-pneumonia in the second case and influenzal pneumonia in the third case. In none of these cases was death due to the vaccination. Two other children died before the vaccination had conferred tuberculin sensitivity and therefore at the time of their death were not completely vaccinated. One of these children died from a hemorrhagic diathesis, probably sepsis, the other from bronchopneumonia. The children just mentioned are the only ones of those inoculated up to the present who have died and who had not yet been exposed to tuberculous infection. Of the children who had been exposed, only two died; I shall refer to these deaths later.

at birth and who at the last after-examination were at least 1 year of age, only four had died in their first year of life. This corresponds to a mortality rate among infants of only about 3 per cent. The method in which we have organized the work of antituberculous vaccination, by caring for the children in an institution or private home during their early life until the vaccination has taken has accordingly not involved any increased risk for the child. That the infants' state of health has been so good is no doubt due to the fact that they were nursed at an institution in which they could be fed on breast milk.

In regard to the living children, numbering 120, who have not yet been exposed, it should be mentioned that at the periodic reexaminations they were all in good health. They were still living in their homes, so far free from tuberculosis, or were accommodated in the homes of healthy families or were admitted to an institution

The children who are of most interest are, of course, those who have been exposed to tuberculous infection after being vaccinated. In the following remarks I shall confine myself entirely to these 230 children. The ages of these exposed children at the time of vaccination will be seen in table 3.

Fully one third of all the children were vaccinated shortly after birth, while but a small number were vaccinated during school age. Thus, vaccination has been performed chiefly on infants and preschool children. In order to form an estimate of the degree of protection that a vaccination may be expected to afford, it is important to know the age at which the exposure to infection began. The earlier a child contracts a virulent infection the more serious does the tuberculous disease in general tend to be. Since, under the most favorable conditions, sensitivity to tuberculin is delayed

for about one and one-half months after vaccination has been performed, it is obvious that no child has been exposed until the expiration of this time. This feature is in itself a very great gain in a prophylactic respect. For various reasons quite a number of the vaccinated children were kept away from their tuberculous homes for a still longer period. I should like to point out that we have not, of course, urged that a child be returned to its home immediately after the vaccination has taken. On the contrary, we have tried to induce the parents to wait as long as possible before taking the child home. The time at which the children were first exposed to infection appears in table 4.

It will be seen from this table that only six children were exposed to the risk of infection at the age of 6 weeks, forty-five were exposed under the age of 3 months and seventy-nine under the age of 6 months; that is, nearly half of the children were vaccinated before 1 year of age. On the other hand, the exposure of some of these children was delayed until they were more than 2 years of age.

Another thing that is important for the effect of a tuberculous infection is the duration of the exposure. Here, too, the prognosis differs in the case of a child who has been exposed to infection ever since infancy

Death rate from tuberculosis among infants per thousand (black columns) and from pulmonary tuberculosis among adults per 10,000 (white columns) in Gothenburg during the years 1912-1933, arranged in five year periods.

from that in a child who is exposed at a later age. The duration of the exposure is seen in table 5.

The shortest period of exposure was fixed at two months. This was done in view of the fact that any eventual tuberculous changes produced by a virulent tuberculous infection cannot be demonstrated until the end of the tuberculous incubation period, about six to seven weeks. Hence children who have been exposed for less than two months after being vaccinated have been regarded as nonexposed. Nearly three fourths of all children exposed during the first year of their lives have been exposed for a period of more than twelve months and some of them up to from six to seven years. Owing to the fact that many of the sources of infection died one after the other, the number of children exposed for very long periods consequently become fewer and fewer in proportion. The children which have only been exposed sporadically have been recorded separately. Usually the risk of a sporadic exposure is not so great as that of a daily one. Several of the children recorded as being continuously exposed have, in addition to the period of exposure shown in table 5, been exposed sporadically at certain times.

All vaccinated children are examined at least once a year and are besides kept under the regular supervision

of the dispensary. As soon as a child exhibits any symptoms of disease it is at once sent for a control examination in addition to the annual reexamination.

In judging the health of a child vaccinated with BCG regard must be paid chiefly to tuberculous disease. In the case of an unvaccinated child a positive tuberculin reaction constitutes an important support for the diagnosis of tuberculosis. In the case of a vaccinated child, on the other hand, no diagnostic significance is to be attached to a positive tuberculin reaction; all children successfully vaccinated with BCG are sensitive to tuberculin.

If the virulent infection, which sooner or later takes place by way of the respiratory passages in a vaccinated child exposed to tuberculous infection at home, should lead to so violent a reaction that anatomic changes arise, these lesions will be found, with but few exceptions, to be intrathoracic. These foci do not usually present any physical symptoms but may be demonstrable by roentgen examination. The only possibility of forming an objective conception of a vaccinated child's state of health as far as tuberculosis is concerned is therefore by means of a roentgen control. An after-examination that is not based on such a control is unreliable and is of no real value from the point of view of morbidity.

All children vaccinated with BCG at Gothenburg who have been exposed after the vaccination to the risk of infection have been examined roentgenologically at least once a year. The results of these after-examinations are seen in table 6. Only one of the 230 exposed children exhibited roentgenologically an infiltration of the hilus of a decided tuberculous character.

This patient was a boy, whose father and a grown-up brother had open pulmonary tuberculosis. The child had been vaccinated shortly after birth and was returned home after the completion of the vaccination. He was then 6 months old. After an exposure of six months he became ill with fever and displayed symptoms of a catarrhal condition of the upper respiratory passages. The roentgen examination showed a density of the hilus and the lower part of the right lung. Virulent tubercle bacilli were discovered in the fluid obtained by gastric lavage, and the diagnosis was clear. The densification was the manifestation of a tuberculous process produced by a virulent infection which the child had contracted at home.

The tuberculous process presented by the boy was remarkably benign. He became afebrile after a week and his general condition was never affected. Although he passed through a whooping cough during his stay at the hospital, he was discharged after five months. Subsequently roentgen examinations have disclosed a rapid disappearance of the densification of the hilus, so that a year after its manifestation the roentgenogram showed an almost normal condition. I may add that this boy's sister, aged 6 years, who had not been vaccinated, was also infected at about the same time after a short visit at home. There resulted an extensive infiltration of the right hilus, for which she had to be nursed at the hospital an entire year.

In four cases the hilus pictures were slightly larger than normal but in three of them the patient had had pertussis or pneumonia before the examination, and not one of these four children had exhibited any symptoms suggestive of a manifest primary tuberculosis. In seven of the cases it was not possible to decide from the roentgenogram whether the hilus shadow was normal or not. In the remaining 216 children alive at

the time of the last reexamination the roentgenograms showed absolutely normal conditions.

Only two out of the 230 children exposed have died, neither of them from tuberculosis. One of the two died from an epidemic meningitis after an exposure of one and three-fourths years. No signs of tuberculosis were found at autopsy. The other child succumbed to an acute pneumonia and diaphragmatic hernia after an exposure of six months. At autopsy no tuberculous disease was discovered.

As to the value of the statistics of the after-examinations, not a single one of the vaccinated children missed the examination. Every one has been controlled and therefore there is no child in my material whose fate is not known.

There is no possibility of determining the manner in which the immunity acquired by means of the vaccination has influenced the results. We have no control material of unvaccinated children who have lived under the same conditions as the vaccinated ones. Even other factors besides a specific resistance may have been active. Attention has already been called to one such important factor: the children were not exposed during their earliest age, and in many cases the exposure was delayed until after 1 year of age and even later. Another favorable factor is the increased interest in the prophylactic measures against tuberculosis shown by the parents of the vaccinated child, thanks to the educational work of the dispensary nurses while the children are being vaccinated. Under the influence of this instruction the parents do everything in their power to prevent severe infections of the children and avail themselves of the prophylactic means at their disposal.

The effect of all these favorable factors contained in the method of vaccination employed can be seen by comparing conditions prevailing when this system was not in use. As already stated the vaccinations have been made at the request of the dispensary. It was also pointed out that this dispensary supervises nearly all tuberculous families in the town and is informed of all children exposed to infection in such families. Attention was finally called to the fact that practically all infants exposed to the risk of infection, but so far uninfected, have been vaccinated. Since deaths from tuberculosis among infants as a rule occur among those in infectious surroundings, this attempt at the reduction of tuberculosis, aimed at by these vaccinations, must have an effect on the total death rate from tuberculosis in infancy in Gothenburg. This is really the case. A prophylactic measure, such as the one described here, cannot of course prevent every death from tuberculosis occurring among infants. Those children who have been infected before the discovery of the source of infection cannot be protected and some of them die from tuberculous disease.

The result of the prophylactic vaccination introduced in 1927 can be seen from the chart, in which, arranged in five year periods, the absolute number of deaths per thousand from tuberculosis among infants in Gothenburg is shown. In the three five year periods immediately preceding 1927 the death rate was 4.3, 4.2 and 3.4 per thousand, respectively. In 1927, which was a year of transition with but a relatively small number of vaccinated children, the mortality amounted to 3.9 per thousand. After 1928 it can be considered that the principles advanced here have been strictly applied. The rate of mortality during this five year period was only 1.4 per thousand; that is, about 60 per cent less than during the preceding period. In 1933, the first

year in the next five year period, the death rate was only 0.3 per thousand. It should be noted that the general tuberculosis death rate, especially from pulmonary tuberculosis, has not shown the same downward tendency. This signifies that the number of the sources of infection has not, broadly speaking, decreased in proportion to the decrease in the number of deaths from tuberculosis in infants.

The course of this mortality curve furnishes conclusive proof that the principles on which we have been working have been efficacious in a purely practical application of BCG vaccine as a prophylactic measure against tuberculosis in the infants of a community. What has been possible for us to achieve should also be attainable elsewhere. The main condition of success is that the work of the dispensary of the community should be based on sound principles and that it has full information about the tuberculous homes. Further, it is essential that vaccination with BCG be performed in such a manner that an immunizing effect can be obtained before the children are exposed.

Gothenburg Children's Hospital.

THE TREATMENT OF EXTENSIVE MALIGNANT LESIONS OF THE STOMACH

WALTMAN WALTERS, M.D.

ROCHESTER, MINN.

It is difficult to define "extensive" carcinoma of the stomach, for a very small, apparently localized, carcinoma no larger than 1.5 cm. in diameter may be of very high degree of malignancy, and it may cause involvement of the lymph nodes along the greater and lesser curvatures of the stomach that necessitates removal of an extensive portion of the stomach and its attached omentums containing the involved lymph nodes. Were it not for the varying degrees of malignancy, extensive malignant tumors of the stomach might be defined as those which, because of their size, necessitate removing an unusually large part of the stomach and, in some cases, even the entire stomach; or those which because of frequent attachment of the carcinoma to adjacent structures, such as the capsule of the liver or pancreas, or because of involvement of the transverse mesocolon, require that portions of these structures also be removed.

Not uncommonly, in this group of cases, preoperative clinical and roentgenologic examination of the stomach may give the impression that the lesion is inoperable but, at exploration, removal may be found to be not only possible but also justifiable. Last year, at the clinic, 126 patients were operated on for carcinoma of the stomach. In 62.6 per cent of cases the lesion was removed by partial or by total gastrectomy. In thirty-seven of these cases the carcinoma was very extensive, and fluoroscopic and roentgenographic examination seemed to indicate that the lesion was of doubtful operability or was wholly inoperable; yet, in nineteen of the thirty-seven cases, the lesion was removed successfully. The corollary of this should be, I think, that every patient who has a malignant lesion of the stomach and whose condition warrants an abdominal exploration should be given the opportunity

From the Division of Surgery, the Mayo Clinic.
Read before the Section on Surgery, General and Abdominal, at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

unless definite evidence of incurability or of remote metastasis is present. I would estimate that, in at least 10 to 15 per cent of cases in which the lesion on roentgenologic examination would appear to be inoperable because of its extent, surgical removal of the lesion can be accomplished. Large malignant lesions of the stomach often will be found to be of a low degree of malignancy, to be sharply demarcated, and to present no glandular involvement; removal of such lesions by partial gastrectomy gives a high incidence of permanent cure, and this particularly is true in cases in which patients are elderly.

Progress that has been made in the treatment and curability of carcinoma of the stomach can be attributed, among other things, to (1) greater recognition of the fact that early symptoms may be insignificant, (2) increasing efficiency with which the competent roentgenologist can identify even the smallest gastric lesions, thus permitting earlier and complete removal, (3) a working hypothesis that every gastric lesion may be malignant unless proved otherwise, and (4) extension of the field of operability to include extensive carcinomas that heretofore might have been regarded as being on the borderline of operability.

VALUE OF THE ROENTGENOGRAPHIC EXAMINATION

The value of the roentgenographic examination in cases of small carcinomas of the stomach is strikingly illustrated in two cases. In the first case, that of a man aged 32, the presence of a small ulcerating lesion, measuring 1.9 by 1.7 cm., was detected by the roentgenologist and diagnosed as an ulcerating carcinoma because of the meniscus sign of Carman. At operation, with the lesion between my exploring fingers, I could not distinguish it from a benign lesion. Microscopic examination following gastric resection revealed it to be a carcinoma of grade 3. Some time ago I operated on a patient who had a small ulcer of the lesser curvature of the stomach; this ulcer had recurred two years after reported local excision of a gastric ulcer elsewhere, and symptoms had recurred. The roentgenologist reported a gastric ulcer with a small crater. At operation, the lesion appeared grossly to be a benign gastric ulcer, with a round, smooth crater approximately 1 cm. in diameter. Gastric resection was performed, the Billroth I-Haberer anastomosis being used to restore continuity between the stomach and the second portion of the duodenum. Although on gross examination the lesion appeared to be benign, a few minutes later a report of microscopic examination indicated that it was a carcinoma.

In the first of these cases the roentgenologist was correct in his declaration that the lesion was malignant but, in the second case, it was not known that the lesion was malignant until it had been so reported on microscopic examination. Of a group of eighty-two cases taken at random, in which patients were operated on at the clinic in 1933 and in which a preoperative clinical and roentgenologic diagnosis of gastric ulcer was made, in seventeen cases, or 20 per cent, the lesion was found to be carcinomatous, and in eleven of these seventeen cases the lesion was inoperable owing to its extensiveness or to metastasis. Carcinoma of the stomach can be detected by a competent roentgenologist in 95 per cent of cases, and roentgenographic examination of the stomach of patients 40 years of age or more who have indeterminate dyspepsia is the most important procedure in the examination, and it never should be omitted in

any suspicious cases. In the absence of the meniscus sign, the roentgenologist cannot determine whether the ulcer is benign or a small ulcerating carcinoma. For this reason, every gastric lesion should be regarded as being malignant or potentially so until proved otherwise.

There is no denying the fact that many small benign gastric ulcers, particularly those of short duration, may heal completely under a properly conducted medical regimen. However, such a method of treatment should not be instituted unless the patient can be kept under constant observation for several months to eliminate, subsequently, the possibility of malignancy. McVicar, several years ago, called attention to the fact that an ulcerating lesion of the stomach that disappears following a course of medical treatment cannot always be assumed to be benign, and he drew attention to the fact that many patients with ulcerating lesions of the stomach responded temporarily to medical treatment even when the process was malignant. The decision to treat a patient with an ulcerating gastric lesion by medical measures carries a great responsibility, for, if the lesion is malignant, by the time it is found to respond unsatisfactorily to medical treatment sufficient time may have elapsed for it to have become completely unremovable. The large gastric ulcer, even though benign, usually is of the callous or penetrating type, extending through the gastric wall either into the pancreas or into the gastrophatic omentum. The possibility of curing such a lesion by medical measures is small; indeed, the possibility that the lesion is malignant is much greater.

I have mentioned this problem of the small gastric ulcer because it seems to me that the recognition of the fact that it frequently is malignant, as likewise may be other small lesions of the stomach such as polypi, will frequently enable an earlier attack to be made on such lesions while they are in stages most favorable for cure. If further progress is to be made, therefore, in securing a larger proportion of three and five year cures in cases of carcinoma of the stomach, every effort must be made to recognize the presence of malignant gastric lesions in their earliest stages before extension of the lesion has occurred.

Just as roentgenologic examination is of great value in the localization of small gastric lesions, so also is it equally valuable in cases of more extensive lesions. In the interpretation of roentgenograms in such cases it must be remembered that the roentgenographic film may present a shadow which would indicate deformity but that this deformity may be the result of other intrinsic, benign gastric lesions, such as foreign bodies, leiomyomas, polypi and large, penetrating, benign gastric ulcers, and that most of these lesions are benign and removable. Certain extrinsic lesions, such as are associated with empyema of the gallbladder or cyst of the pancreas, often produce deformity of the stomach suggestive of a gastric lesion. In either of these groups, if a large portion of the stomach appears involved on roentgen examination, the lesion might be regarded as inoperable and malignant unless exploration is done.

EXTENSION OF THE FIELD OF OPERABILITY OF MALIGNANT GASTRIC LESIONS

In general, I believe that an increasing number of extensive malignant lesions of the stomach are being removed. This has partially been due to the fact, as I mentioned previously, that every patient who has a lesion of the stomach, no matter how extensive that

lesion appears to be, is never denied the possible benefits of an abdominal exploration, provided his general condition permits it and provided remote metastasis is not demonstrable. The finding of an extensive carcinoma localized in the stomach, or even of one with associated glandular involvement, is viewed from the standpoint that unless the lesion is removed the patient is doomed to an early death. On the other hand, Balfour has shown that, when the disease is still confined to the stomach, 50 per cent of patients who have a carcinoma of the stomach which potentially is removable have lived for three years or longer following partial gastrectomy, and that, even when extragastric glandular involvement has taken place, 19 per cent of patients have lived three years following resection.

In several cases total gastrectomy has been performed successfully at the clinic, and patients have lived and been comfortable two and three years subsequently. That such an operative procedure can be carried out in suitable cases with great benefit to the patient has led to the impression that all gastric lesions should be removed unless they have invaded adjacent structures to the extent that the carcinomatous process cannot be removed in its entirety. At operation, in many instances in which the lesion at first would appear to be insusceptible of removal because of its extent and attachment to the mesocolon and to the capsule of the pancreas or liver, it is found that, after freeing of adhesions and separating the lesion from these structures, the growth is readily removable. In other cases, particularly if the tumor is large, the uninvolved portion of the stomach may be thickened to give the appearance of involvement, yet the thickening may be only the result of gastritis adjacent to the lesion. It is not an uncommon experience to find that a growth which is examined while the patient is straining under light anesthesia appears to be unremovable but under deep anesthesia may be seen to be readily removable. In several cases involvement of the transverse mesocolon has given, at first, the appearance of inoperability, yet it usually is the avascular portion of the mesocolon that is involved, and this portion can be removed with the carcinoma without interfering with the blood supply of the colon.

THE INFLUENCE OF AGE ON OPERATIVE RISK

I believe it is worth while emphasizing to patients in the sixth, seventh or even eighth decade of life that they frequently stand operative procedures of great magnitude as well as younger individuals. One of the two successful total gastrectomies I have performed for carcinoma was in the case of a man 68 years of age, and he was living and well two years later. Two years ago I performed subtotal gastrectomy in a case in which the patient was 80 years of age, and he has been free of recurrence since that time. I recall many cases in which patients in the sixth and seventh decades of life were operated on successfully and in which extensive gastric resections were carried out successfully with a risk no greater than that attending resections of average extent among much younger patients. A corollary of this is that it is not the age of the patient but his general condition that is a factor in the surgical mortality.

TECHNICAL PROCEDURES ASSISTING IN THE REMOVAL

I have found it of value to approach all extensive lesions of the stomach through a left rectus incision.

Such an approach enables one to attack the upper part of the stomach with much greater ease than through an incision in the median line. Resection is begun by dividing the duodenum just below the pyloric sphincter and by reflecting the stomach upward, removing all of the gastrohepatic omentum and as much of the gastrosplenic omentum as may be indicated to a point well above the lesion. If it is desired to perform a Polya type of anastomosis, the jejunum is sutured to the posterior wall of the stomach at this high level before the growth is removed, which enables one to remove a large part of the stomach or even the entire stomach when necessary, with greater ease and safety than by removing the lesion first, using a crushing clamp to close temporarily the proximal end of the stomach. Among fleshy individuals particularly, removal of all the gastrosplenic omentum to the site of resection assists materially in the ease with which reconstruction anastomosis can be carried out and, at the same time, more completely removes any involved glands along the greater curvature.

In general, a posterior Polya, or an anterior Polya-Balfour, type of anastomosis is the most satisfactory type of reconstruction following extensive gastric resection for malignant disease. However, in certain instances I have found that the original method of Billroth, in which the stomach is anastomosed to the duodenum, has worked out to advantage, although the greatest field of its applicability is with benign, gastric ulcers, bleeding duodenal ulcers, and with recurring ulcers. This particularly is true of small lesions localized high on the lesser curvature of the stomach, the removal of which can quite readily be effected by removal of a larger portion of the lesser curvature and its omentum. By preserving a larger amount of the greater curvature of the stomach, anastomosis to the duodenum directly requires less time than the Polya anastomosis, and there is one less area for suturing. When extensive gastric resections have been performed on elderly patients, particularly in the case of subtotal or total gastrectomy, jejunostomy as a means of providing a temporary method of feeding has a decided advantage, as nourishment can be administered directly into the jejunum through a tube for as long a time as necessary; during this time oral administration of fluids is restricted to assist in healing the anastomosis. This is of particular value for patients who have lost a considerable amount of weight and who have been debilitated as a result of carcinomatous obstruction.

SUMMARY

Because of the varying degrees of malignancy of carcinomatous lesions of the stomach, probably all malignant gastric lesions should be regarded as extensive, for the very small lesion may be highly malignant and produce glandular involvement and a larger lesion may be of a low degree of malignancy and produce no glandular involvement. Since very large malignant lesions of the stomach are usually localized in the stomach and frequently are of a low degree of malignancy, it is quite necessary that every attempt be made to remove them. Frequently such lesions, in the preoperative clinical examination, particularly in the roentgenologic examination, may appear to be, because of their size and extent, inoperable; yet on abdominal exploration these lesions frequently can be removed successfully. In addition, the fact that certain other intrinsic gastric lesions, such as polypi, large gastric ulcers or foreign bodies, as well as some few extrinsic

lesions, may deform the stomach to the extent that the lesion appears malignant and inoperable, even though it is benign and removable, emphasizes further the value of abdominal exploration. The finding of an extensive carcinoma localized in the stomach, even when there is associated glandular involvement, is viewed from the standpoint that unless the lesion can be removed the patient is doomed to an early death. It is felt that such a patient should not be denied the benefit of surgery if it is possible to remove the growth. Balfour's report of 50 per cent three year cures in cases of removable gastric lesions without glandular involvement and of 19 per cent three year cures in cases of very malignant lesions with glandular involvement emphasizes the great value of surgical removal of all gastric carcinomas.

Technical procedures assisting in removal of extensive gastric lesions are to approach the stomach through a left rectus incision, to begin resection by dividing the duodenum below the pylorus, and to complete the posterior portion of the gastrojejunal anastomosis to the posterior wall of the stomach high above the lesion before the latter is removed. This enables a larger segment of the stomach to be removed. A temporary jejunal stoma for feeding has permitted administration of nourishment into the intestinal canal during the post-operative period in which healing of the anastomosis is taking place. If further progress is to be made in securing a larger proportion of cures in cases of carcinoma of the stomach, every effort must be made to recognize the presence of malignant gastric lesions in their earlier stages, and in this roentgenologic examination of the stomach is of the greatest assistance. Competent roentgenologists have been able to identify accurately and to localize a polypoid or an ulcerating gastric lesion as small as 1 cm. in diameter.

ABSTRACT OF DISCUSSION

DR. FRANK H. LAHEY, Boston: In discussing carcinoma of the stomach, one must always assume the position that the diagnosis of this condition is too frequently late, owing to the fact that the symptoms are of such a silent character. Progress in this condition will not be made until symptoms can be investigated by bismuth subnitrate roentgenograms oftener and earlier. One thing that always comes up is the question of malignant degeneration of ulcer. There are certain points about these cases that are now quite settled. One is that 100 per cent of the lesions on the greater curvature are malignant. I do not hesitate to submit lesions in this location to immediate surgery. The next location in which malignancy is common is the prepyloric region. The closer to the pylorus on the gastric side the lesion is, the greater is its tendency to be malignant. Lesions in this region, however, are easily misinterpreted because prepyloric spasm is very common and I have twice found no lesion on exploration. Prepyloric spasm closely simulates a malignant condition. Another point of value to discuss is the type of malignancy that involves the whole stomach and appears inoperable. One sees two types of cancer of the stomach: one, the lesion that involves the serosa, particularly on the lesser curvature, and this very quickly metastasizes into immediate and distant lymph nodes; the other type, the so-called leather bottle stomach, the linitis plastica type. Microscopic examination reveals two different types of cancer distribution. In the linitis plastica type the cancer cells tend to stream down between the muscle bundles and in this way they are disseminated through the entire gastric wall. They tend to expend their energy in this type of carcinoma not in distant metastases. In the other type of carcinoma, the localized type, the carcinoma cells are localized to the lesion but extend out in the lymphatics and do tend to metastasize early. Not infrequently, therefore, one sees almost complete

involvement of the stomach by the linitis plastica type of carcinoma without metastasis in the liver and without metastatic lymph nodes. I think these are the cases particularly in which total gastrectomy is best indicated. My associates and I have had three successful total gastrectomies. Dr. Clute had one and I had two. As one becomes adjusted to some of the technical difficulties of this operation and if the cases are well selected, it is distinctly a reasonable and possible procedure but will frequently, of course, as Dr. Walters has already stated, be disappointing in the long run because of recurrences due to the extensiveness of the lesion. Nevertheless, when I recall that Dr. Clute's successful case had been repeatedly rejected elsewhere as inoperable but, following a total gastrectomy, the patient worked every day and lived in comfort for three and a half years, this operation becomes, in my mind, definitely justifiable.

DR. GATEWOOD, Chicago: Until some new light is shed on the treatment of carcinoma, extensive gastric resection will continue to be a necessary procedure. Neglect will always play a part, but in spite of all that lay cancer education and periodic health examination can do, gastric cancer frequently sneaks up on its unsuspecting victim so silently that it is extensive before he has any warning. Theoretically, more than three fifths of gastric cancers should be amenable to eradication by surgery. Practically, less than one fourth can be removed. How are results to be improved? First, by more careful heeding of any vague gastric symptoms in the patient past 40 (thereby making earlier diagnoses) and, secondly, by improving therapy. Reviewing the last twenty-five consecutive hospital deaths following gastric resection done for carcinoma, I find the following causes: I. Peritonitis, eight cases. A. General. B. Local, as subphrenic abscess. II. Pneumonia, eight. III. Cardiac failure, two. IV. Shock, three. V. Hemorrhage, one. VI. Pneumothorax, one. (This patient died rather suddenly several hours after total gastric resection. Autopsy showed that, by retching, a small opening had been blown in the suture line. As the diaphragm had been used to reinforce the suture line, the swallowed air was forced into the thoracic cavity). VII. Inanition, one. VIII. Pulmonary metabolism, one. It was found that the absence of free acid definitely increases the operative risk, owing to the great increase in bacterial flora. While I have not been able by my own microscopic studies to confirm Bloomfield's statement that absence of hydrochloric acid is due to gastritis, tissues are definitely more friable and the mortality greater in the achlorhydria case. To reduce hospital mortality, careful preoperative preparation is most essential. A week can often be well spent in bringing up the patient's fluid balance, in repeated blood transfusions and in feeding the patient small amounts of highly nourishing foods at frequent intervals. Drachm (4 cc.) doses of dilute hydrochloric acid given from three to five times a day are, I believe, of definite value in reducing the bacterial content of the stomach. Gentle lavage by the Levine tube except in cases of active bleeding aids in preparation as well as accustoming the patient to a procedure that may be of life-saving value later. In selected cases I have inserted the tube under the fluoroscope postoperatively, obviating the necessity for jejunostomy. Earlier diagnosis and more technical skill are of great importance, but physicians should not forget to direct attention toward more careful preoperative and postoperative care.

DR. J. TATE MASON, Seattle: I have had occasion within the last two years to do two total gastrectomies, which have called attention to several outstanding technical advantages in certain operative procedures. First, if the surgeon is able to do a total gastrectomy at all it is a relatively easy surgical procedure in that individual. The patient with a large frame, who has lost considerable weight, is of course much easier to operate on than the short, thick, heavy-set person, in whom exposure is always difficult. The operation is greatly simplified by following Dr. Walters' method of using the stomach, after it has been thoroughly detached, as a lever to pull down on while making the posterior anastomosis between the esophagus and the jejunum. I have in the past classified certain patients with cancer of the stomach as inoperable, because of their clinical and roentgenologic appearance, who should have been given the chance that exploratory operation affords. Both my

patients made uneventful recoveries. One lived very comfortably for twelve months and then began to have symptoms of recurrence and died in fourteen months. The other patient was operated on too recently for a report. I know of no operation in the abdominal cavity in which one needs more exposure than in a total gastrectomy. Particularly is this true in certain individuals. I have for years used a zigzag incision, which gives the greatest amount of exposure that I have ever seen through any abdominal incision, in which no nerves or muscle fibers are severed, and which, when closed with a little care, gives as few postoperative hernias as any incision I have seen. The incision begins high up on the left rectus and passes down in this muscle to just above the umbilicus and then is carried across to the opposite side and down on the right rectus a short distance, depending on the amount of exposure one wishes to obtain. The anterior sheath of the left rectus is then opened on its inner third, the muscle fibers containing the blood supply and nerve supply rolled to the other side. Just above the umbilicus the fascia is cut straight across, and the same procedure is followed on the right rectus below the level of the umbilicus, the muscle being rolled to the other side. In closing this incision, one closes the transverse part first, which is usually imbricated, making the fascia even more secure and tight than before operation.

DR. J. SHELTON HORSLEY, Richmond, Va.: The only cure for gastric cancer is excision, so the problem of treatment is simple. There are a few cases of small, round-cell cancer of the stomach and cases of lymphosarcoma which respond to irradiation, but they are rare. As a practical therapeutic measure, excision of a gastric cancer is the accepted treatment. It is obvious that the diagnosis and resection should be done early, but the majority of cancers of the stomach are seen only in the advanced stages and they demand earnest consideration. The statement by Dr. Walters that almost all gastric cancers should be explored is important. Naturally, when there is ascites, or Virchow's glands, at the root of the neck, or when masses in the culdesac can be felt by rectal examination, exploration is contraindicated. But without these signs of hopelessness, even though an experienced roentgenologist says that he thinks the lesion is inoperable, exploration is often justified. I have had several cases in which the roentgenologist pronounced the lesion inoperable and in which I was able to make a resection. A few of these patients have at least had their lives prolonged, all otherwise being doomed. The administration of large quantities of dilute hydrochloric acid, a physiologic antiseptic, is valuable. This, with intravenous dextrose in Ringer's solution, will frequently convert into a potentially safe recovery a case that otherwise seems desperate. A resection may often be done in the presence of adhesions or invasion of the adjacent viscera, or even in the presence of small metastases in the liver. It not only removes the cause of obstruction, frequently a necrotic cancerous mass, but likewise gives a free exit to the stomach contents. I doubt whether gastro-enterostomy really has any place in the treatment of cancer of the stomach, because if this is the only operation that can be done because of the extent of the lesion, a gastro-enterostomy will afford no real relief. Pathologists have shown that about 23 per cent of all deaths from gastric cancer show the lesion still limited to the stomach. The small amount of resectability that is reported from the hospitals suggests that chances should be taken in many cases that seem inoperable. If 23 per cent of gastric cancers at necropsy are confined to the stomach, there certainly should be a still larger percentage limited to the stomach when the patient comes for diagnosis.

DR. J. W. THOMPSON, St. Louis: I wish to stress a point that has not been emphasized and that is the frequency of the extension of these carcinomas onto the transverse colon. The decision as to the operability of the lesion on abdominal exploration is frequently based on the extension of these peritoneal implants from the original growth. About three years ago I had occasion to perform an extensive subtotal resection on such a patient and at the same time I made a primary end-to-end anastomosis after resecting 6 inches of the transverse colon. This man has lived three years in comfort. The colon can be resected successfully at the same time that the stomach is resected.

THEORY AND PRACTICE OF PARENTERAL FLUID ADMINISTRATION

ALEXIS F. HARTMANN, M.D.

ST. LOUIS

In the early stages of undue loss of water from the body, regardless of the cause of such loss, the composition of the blood in respect to its water content and electrolyte pattern tends to remain unaltered because of the stabilizing or buffering effect of the intercellular fluid of the body. This portion of the body may be looked on as a reservoir which may shrink appreciably in order that changes in the blood and perhaps also in the fixed tissue cells may be kept at a minimum. When, however, the intercellular fluid becomes exhausted, changes do appear in the blood indicative of this exhaustion, and probably also in the fixed tissues themselves. The nature of the changes is largely dependent on the manner in which fluid is lost; sometimes acidosis may accompany dehydration, at other times alkalosis, while occasionally a tendency toward one such change may be almost exactly balanced by a tendency in the opposite direction (chart 1). Also, during a period of excessive fluid loss leading to dehydration, the groundwork for subsequent edema may be laid.

By chemical examination of the blood one can usually obtain undeniable proof of loss of water, chloride, bicarbonate and total fixed base. Loss of other substances, however, such as potassium and calcium, are not usually so indicated, as their concentrations in the blood plasma tend to remain quite fixed, the tissue cells and the bones acting as reserve depots. These facts should be borne in mind when efforts are to be made to replace lost intercellular water, so that restitution may be chemically adequate. Thus, it is frequently necessary to replace lost electrolytes along with water, if the effects of dehydration are to be overcome completely. It may also be necessary to restore plasma protein, or at least to make more normal the colloidal osmotic pressure of the blood in order to reestablish a normal circulation of the blood and a normal interchange of substances between the blood and the intercellular fluid.

In order to accomplish such a purpose without too much reliance on the aid which renal activity may afford or on the aid with which absorption of food from the intestinal tract may provide, it may be necessary to give parenterally fluids that are quite similar to normal intercellular fluid, or at least to provide the most essential mineral constituents of body fluids. Sodium chloride is the most important salt as far as amount is concerned. It is to be expected, therefore, that administration of isotonic sodium chloride solution should go far toward relief of the phenomena of dehydration. Sodium chloride alone, however, frequently is insufficient to provide complete relief of symptoms.¹ The addition of potassium and calcium is at least theoretically indicated, and when such an addition is made in the same proportion in which these elements exist in blood plasma or intercellular fluid, Ringer's solution

From the Department of Pediatrics, Washington University School of Medicine, and the St. Louis Children's Hospital.

Read before the Section on Pediatrics at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

The Effects of Diarrhea, Vomiting, Dehydration and Oliguria on the Acid-Base Balance of the Plasma of Infants with Mastoiditis. *Am. J. Dis. Child.* 35: 557 (April) 1928; Acidosis, Alkalosis and Ketosis, in Brennenmann's Practice of Pediatrics, Hagerstown, Md., W. F. Prior Company, Inc., volume 1, section 2, chapter 1.

without causing reactions. It has been my policy, however, to make fresh solutions every week. Commercial products in ampule form may also be used if dilutions are made with freshly distilled sterile water before injection. My experience has been entirely satisfactory with such preparations.

For intraperitoneal injection, however, special precautions must be taken. Perhaps the best method is that described by Schwentker,⁵ in which chemically pure dextrose is sealed in glass ampules and sterilized by boiling in a water bath for thirty minutes on each of three consecutive days. Just before using, the dry dextrose is dissolved in freshly distilled water to make an isotonic 6 per cent solution. In my own experience, however, distention has so frequently followed the intraperitoneal administration of dextrose that it is no longer given by this route. The explanation for such an undesirable reaction is suggested by the recent work of Darrow and Yannet,⁶ who found that, when dextrose is injected intraperitoneally, electrolytes and water are first withdrawn from the blood until the fluid within the peritoneal cavity resembles the blood and intercellular fluid in its electrolyte composition.

Sodium Bicarbonate Solution.—This should be made up freshly before using. For intravenous injection, it is satisfactory to transfer chemically pure anhydrous sodium bicarbonate onto a clean filter paper taken from the middle of a pack with a flamed spatula. In this way the proper amount of sodium bicarbonate may be weighed to make a 5 per cent solution, the weighed material being added to cool, freshly distilled sterile water. While not absolutely sterile, this material is suitable for intravenous administration and has been used quite extensively without indications of infection. For subcutaneous injection, a 1.5 per cent solution is made, and a small amount of phenol red indicator is added. The solution is then filtered through a Berkefeld candle and, just before using, carbon dioxide is filtered through water and bubbled through the solution until the red color changes to orange. Such a solution is isotonic, sterile and of a p_H that is not irritating. Theoretically, such a solution should also be satisfactory for intraperitoneal injection, but I have never used it in this way and therefore cannot recommend its use. Another method of preparing sodium bicarbonate is that suggested by Cunningham and Darrow.⁷ By this method previously sterilized sodium carbonate is partially neutralized by hydrochloric acid with the formation of sodium bicarbonate and sodium chloride.

Artificial "Spinal Fluid."—This solution was developed particularly to meet the needs of Dr. Ernest Sachs in replacement of lost ventricular fluid during certain intracranial operations, particularly choroidpexctomy for the relief of hydrocephalus. At the time of injection into the ventricles, this solution closely resembles normal cerebrospinal fluid as far as content of sodium,

potassium, calcium, magnesium, chloride, bicarbonate and p_H is concerned. Because of its bicarbonate content, the solution has to be prepared in two parts, which, after sterilization by autoclaving and proper dilution, are mixed in equal amounts just before using.

Solution 1 (concentrated): Preparation is as follows: sodium chloride, 300 Gm.; potassium chloride, 19 Gm.; calcium chloride, 10 Gm., and magnesium chloride, 20 Gm. are added to 1 liter (1,000 cc.) of freshly distilled water. Filter (preferably through a glass disk filter to exclude filter paper fibers). Autoclave at 15 pounds for thirty minutes. This is the concentrated solution 1 which should keep in pyrex glass indefinitely.

To prepare for mixing with solution 2, measure accurately 10 cc. (with a sterile pipet, so as not to contaminate the stock solution) and make to 250 cc. with freshly distilled water. It is convenient to do this in a 250 cc. volumetric flask. Make up to the mark, and then withdraw 10 cc. with the same pipet, leaving 240 cc. Place this amount in a pyrex glass flask or bottle of 500 cc.

Chart 2.—The chemical composition of normal body fluids and the more common therapeutic solutions for parenteral injection.

capacity, mix, and resterilize by autoclaving at 15 pounds for thirty minutes. Stopper with sterile (autoclaved) cork or rubber stopper. It is usually convenient to prepare about six such bottles of 240 cc. each of solution. This solution may be resterilized at any time, if thought advisable.

Solution 2: Weigh out 5 Gm. of anhydrous sodium bicarbonate. Add a few milligrams of dry phenol red (phenolsulphonphthalein) and make to 1 liter (1,000 cc.) with freshly distilled water. Filter free of any suspended particles. Measure 240 cc. of this solution into a pyrex glass flask or bottle of 500 cc. capacity and sterilize by autoclaving at 15 pounds for thirty minutes. Stopper with a sterilized (autoclaved) cork. In this condition the solution may be resterilized at any time, if thought advisable.

Just before using, add exactly 1 cc. (measured with an accurate sterile pipet) of concentrated hydrochloric acid (36 per cent) to 240 cc. of solution 2, and mix by rotating the flask or bottle. The sodium carbonate should now be converted into sodium bicarbonate plus sodium chloride, and the color should change from red

to an orange shade. If such a change does not occur, a drop more of the acid should be added. At this stage the solution can no longer be reesterilized. Pour equal parts of solution 2 (after the addition of the hydrochloric acid) into solution 1 and mix by rotating the flask. This final mixture has now the composition of normal spinal fluid and is now ready for injection into the ventricles.

Acacia Solution.—While it is possible to prepare acacia solution satisfactorily for intravenous injection, it has proved much more convenient to use products already prepared, such as the product marketed by Eli Lilly & Co. This product is marketed in 30 per cent concentration and contains 4.5 per cent sodium chloride. Its most frequent use is its intravenous injection in cases of shock. For this purpose the original material is diluted five times with sterile distilled water or 20 per cent dextrose solution, so that the final concentration of acacia is 6 per cent and sodium chloride 0.9 per cent. When it is used for the relief of nephrotic edema, such

Sodium Lactate Solution.—This solution is indicated in specific amounts in all types of severe acidosis other than that associated with congenital heart disease with persistent cyanosis. It is of value also for rapid alkalization of the urine in the treatment of acute infections of the urinary tract. Sodium lactate may be administered by any of the parenteral routes. It is important that an isotonic solution be used for subcutaneous or intraperitoneal administration. One-sixth molar sodium lactate is isotonic and is made by adding one part of the molar sodium lactate solution to five parts of sterile distilled water. Somewhat more concentrated solutions may be given intravenously, but, especially during the presence of dehydration, it is unwise to use a solution more concentrated than the isotonic solution. If the carbon dioxide content of the blood is known, the amount of sodium lactate that will be required to raise the carbon dioxide content to the normal value of 60 volumes per cent may be calculated.² Since, however, the chief indication for the use of sodium lactate is the presence of a carbon dioxide content under 25 volumes per cent, a routine dose of 10 cc. of the molar solution per kilogram of body weight, diluted with five volumes of distilled water, will be generally satisfactory; i. e., this amount will tend to increase the carbon dioxide content by 25 to 35 volumes per cent. When merely alkalization of the urine is desired, smaller amounts, i. e., 5 cc. molar solution per kilogram of body weight, are effective.

Lactate-Ringer's Solution.—Since its effect in the body is to relieve either acidosis or alkalosis of the metabolic types, lactate-Ringer's solution is indicated in all types of dehydration, especially when a chemical study of the blood has not been made. When severe alkalosis of the metabolic type is known to exist, the addition of lactate to the Ringer's solution is without benefit, aside from its antiketogenic and glycogenic effects. The addition of lactate to Ringer's solution, however, need not be feared, even if very severe alkalosis is present. The results obtained in

such cases by (1) Ringer's solution, and (2) lactate-Ringer's solution are illustrated in chart 3. When very severe acidosis is known to be present, the amount of lactate indicated is of such an amount that it is much better to give the lactate independently of the Ringer's solution (i. e., as sixth molar sodium lactate), and later, if further fluid administration is necessary, it may be combined with Ringer's solution to prevent recurrence of acidosis.

Lactate-Ringer's solution may be given by any of the parenteral routes. It has almost entirely replaced the use of physiologic solution of sodium chloride or Ringer's solutions in the St. Louis Children's Hospital for the routine treatment of dehydration with or without the knowledge of coexisting chemical changes. When administered by the subcutaneous or intraperitoneal routes or as a single intravenous injection, therapeutic doses should average from 80 to 100 cc. per kilogram of body weight. Mixed with 10 per cent dextrose solution, it has been the fluid of choice for the continuous intravenous drip method of providing fluid.

Sodium Bicarbonate Solution.—The indications for the use of sodium bicarbonate solution are the same as

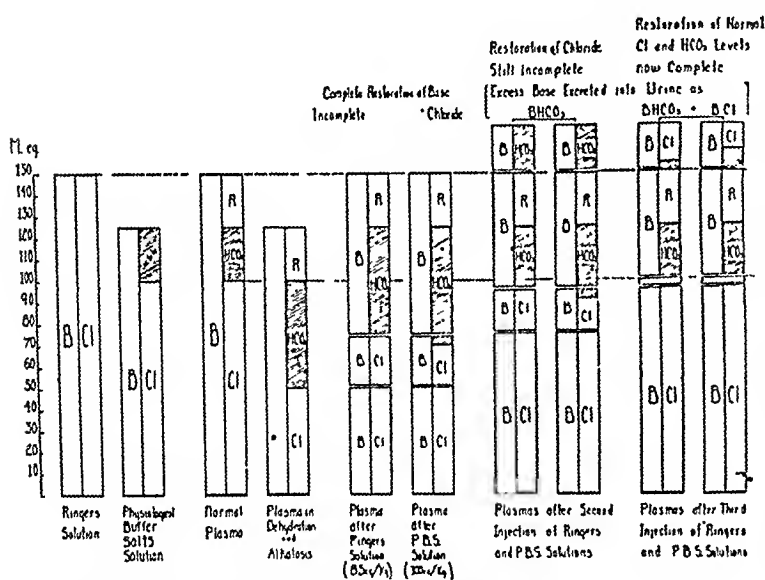

Chart 3—Schematic recovery from severe alkalosis in response to Ringer's solution and to lactate-Ringer's solution.

dilution is unnecessary and the material may be used as marketed or diluted just sufficiently to enable it to flow readily by gravity.⁸

SPECIFIC INDICATIONS

Ringer's Solution.—This solution is indicated whenever chlorides and the fixed bases sodium, potassium, calcium and magnesium have been lost. Therefore it is indicated in all forms of dehydration, but particularly in cases in which large amounts of gastro-intestinal secretions have been lost by vomiting, diarrhea or fistula, as occurs in such conditions as pyloric and intestinal obstruction, diarrhea, diabetic acidosis, glomerular nephritis (terminal stage) and many severe infections. Beneficial effects in acidosis or alkalosis result indirectly from improvement of the circulation and stimulation of renal activity. While Ringer's solution may be administered by any of the parenteral routes, it finds its chief use when administered subcutaneously or intraperitoneally. Ordinarily therapeutic doses, adequate for restitution of lost water and minerals, average from 80 to 100 cc. per kilogram of body weight.

8. Hartmann, A. F.; Senn, M. J. E.; Nelson, M. V., and Perley, A. M. The Use of Acacia in the Treatment of Edema, J. A. M. A. 100: 251 (Jan. 28) 1933

for sodium lactate solution. It is superior to the latter only in those conditions in which lactate metabolism may be seriously impaired (congenital heart disease with anoxemia being the only one that has been encountered so far in my experience), but it has many disadvantages.² A somewhat hypertonic solution may be given intravenously in a case of severe acidosis in a dosage of 0.5 Gm. of sodium bicarbonate per kilogram of body weight. A sterilized isotonic solution containing carbon dioxide in the proper amount may be given subcutaneously in corresponding amounts.

Dextrose Solutions.—Dextrose solutions are indicated when the carbohydrate metabolism is low, when ketosis exists, when hypoglycemia is present, and when there is depletion of liver or muscle glycogen: i. e., in such conditions as starvation, acute severe infections, intoxications, particularly in cases in which the liver and heart muscle are affected, and in hyperinsulinism. It is also of value in promoting diuresis and for this purpose may be used in acute nephritis with acute cerebral edema. Isotonic dextrose solution may be given subcutaneously or intravenously or, as previously mentioned, it may be mixed with equal parts of lactate-Ringer's solution to be given by either of those two routes. More concentrated solutions, even up to 50 per cent, may be given intravenously, when in particular edema is to be treated and when diuresis is particularly to be established. There is some danger of venous thrombosis when 50 per cent dextrose is used, particularly if the circulation is sluggish. Since dextrose solutions are given both for their dextrose and for their water content and for the relief of edema, no exact dosage can be given. In general, when given for purposes of administering fluid, from 80 to 100 cc. per kilogram may be given subcutaneously, and, roughly, from one-fourth to one-half that amount may be given as a single intravenous injection. When given in conjunction with lactate-Ringer's solution by the continuous drip method, the rate of flow should be from 3 to 6 cc. per kilogram hourly after dehydration has been relieved.

Artificial "Spinal Fluid."—The use of this solution has been as yet confined to cases in which operation is performed for hydrocephalus in which it is desirable to refill collapsed ventricles. Theoretically, at least, this solution should be much superior to physiologic solution of sodium chloride whenever replacement of, or admixture with, cerebrospinal fluid is to be considered, in such instances as "through and through" drainage for meningitis, spinal anesthesia and nerve block.

Acacia Solution.—Acacia is especially indicated when the blood volume has been reduced as the result of hemorrhage or shock. In such conditions the injection of electrolytes or nonelectrolyte crystalloids, such as dextrose, does not have much of an effect in increasing the blood volume, since they are free to pass through the capillary walls and actually diffuse quite rapidly into the tissue fluids. The plasma proteins and acacia, however, are normally impermeable, remain in the circulation and through their effect in raising the colloidal osmotic or oncotic pressure tend to maintain blood volume. In nephrotic edema the oncotic pressure of the plasma is reduced because of loss of protein from the blood, chiefly as the result of albuminuria. The glomerular membrane in such conditions is less permeable to acacia than to the plasma proteins, and through its use in such conditions the oncotic pressure of the plasma usually can be restored to a level sufficiently high to

lead to loss of edema fluid. Acacia should be administered only intravenously, the concentration varying from 6 to 30 per cent. The solution injected should have roughly a sodium chloride concentration of from 0.6 to 0.9 per cent. Since the effect on edema of injected acacia depends largely on the concentration of acacia which is maintained in the blood plasma, which in turn is dependent on the amount given in relation to the original blood volume, the rate of excretion into the urine and the rate at which it is taken up by other tissues, the dose of acacia cannot be fixed.⁸ In general, however, from 1 to 2 Gm. of acacia per kilogram of ideal body weight is given intravenously over a period of forty-five to sixty minutes and may be repeated daily until as much as 10 Gm. per kilogram has been given.

Blood.—Specific indications for the administration of whole blood are: (1) reduction in blood volume, resulting from hemorrhage or prolonged malnutrition; (2) severe anemia, particularly if the erythrocyte count is low; (3) blood dyscrasias associated with a bleeding tendency, such as hemorrhagic disease of the new-born and hemophilia; (4) edema which is due chiefly to diminished plasma protein ("nutritional" edema, nephrosis and chronic active glomerular nephritis), and (5) possibly icterus gravis of the new-born and other types of hemolytic anemias. In such instances there is either a qualitative or a quantitative deficiency of whole blood or some of its components, such as erythrocytes, platelets or plasma. As a rule, sufficient whole blood may be given to correct such a deficiency. The most important exception is the edema of nephrosis, in which the protein loss through the kidney may equal or excel the rate at which protein can be injected as whole blood. In such instances, larger amounts of protein may be administered as plasma transfusions or, as is not infrequent, a substitute for protein in the form of acacia must be relied on. In a number of instances of rheumatic heart disease with failure, severe anemia was relieved by transfusing cells suspended in citrated saline solution without running the risk of increasing the cardiac embarrassment by increasing the blood volume or viscosity by adding more plasma protein.

Blood transfusions have also been extensively used in both acute and chronic infections, with the hope of administering antibodies. Probably because of the frequent lack of such antibodies in high concentration, results in such cases have often been disappointing.

In general the intravenous route is the one of choice, particularly if the function of the erythrocytes is to be preserved. The usual amount of blood given in this way is about 20 cc. per kilogram of body weight. More may be given safely in cases of hemorrhage, while in the presence of cardiac or pulmonary lesions it is often desirable to repeat much smaller transfusions (5 cc. per kilogram). In states of severe nephrotic edema, very much larger amounts of plasma may be given, because of the rapid loss of plasma protein by way of the urine. When given subcutaneously or intramuscularly, the erythrocytes are destroyed but the plasma elements rapidly make their way into the blood stream. Under favorable conditions apparently most of the blood given intraperitoneally finds its way rapidly into the circulation. My experience with very sick infants, however, has been discouraging, in that abdominal distention tends to result, and in several instances, most, if not all, of the blood injected was found unabsorbed after death several days later.

Combinations of Various Solutions.—Injection of sodium lactate and Ringer's solution has already been considered. In a similar fashion, dextrose may be combined with Ringer's or lactate-Ringer's solution. As a rule, it is best to mix isotonic solutions in equal volumes, so as to preserve isotonicity. Equal parts of 10 per cent dextrose solution, however, may be added to Ringer's or lactate-Ringer's solution and given intravenously without any deleterious effect. Dextrose and sodium bicarbonate may be mixed, if the resultant mixture is given immediately. On standing, however, dextrose decomposes much more rapidly in the presence of alkali. Sodium bicarbonate cannot be mixed with Ringer's solution without precipitation of calcium bicarbonate. Since acacia solution contains considerable amounts of calcium, bicarbonate solution and acacia are also incompatible for this reason. Acacia cannot be mixed with citrated whole blood either, since the calcium content of the acacia will neutralize the effect of the citrate and permit clotting to occur.

ABSTRACT OF DISCUSSION

DR. ARTHUR G. HELMICK, Columbus, Ohio: Sometime ago I had the opportunity of viewing the immediate effects of fluid introduced into the abdominal cavity. It was entirely new to me and I thought it of sufficient interest to bear repetition. It came about by accident in connection with an operation for pyloric stenosis. In these cases, it is my custom to give 5 per cent dextrose in physiologic solution of sodium chloride subcutaneously. In this particular instance there was a new house officer on duty. The method of administering the fluid not being specified, he gave it intraperitoneally. The next morning some fifteen hours afterward, when the surgeon opened the abdominal cavity, quite a little of the solution was still present as well as a brownish gelatinous substance, which covered the abdominal parietes as well as the intestine. This material did not seem to be a mass but it was evenly distributed over the surface as if it might have been painted on. It was of such a character that it made any type of manipulation almost impossible, and it was only with great difficulty that the operation was completed. The youngster made an uninterrupted recovery from the immediate effects, but a short while afterward there was a recurrence of the original symptoms and an exploration was decided on. This was done. About the seat of the original operation was a dense mass of adhesions. These were broken up, there was great shock, and the child died some hours later. I think two distinct facts can be drawn from this instance: First, one dare not be too dogmatic concerning the rapidity and thoroughness with which the abdomen absorbs fluid, and, second, it is evident that abdominal operations will have to be added to the contraindications already known, to the administration of certain, if not all, fluids intraperitoneally.

DR. JOSEPH C. RAY, Louisville, Ky.: My work in venoclysis has followed closely that of Dr. George A. Hendon of Louisville in adults. We have applied it also to very young persons. Venoclysis is administered by attaching a cannula into the vein for the continuous administration of fluid. The fluid which we have found most successful in administering to children has been a 5 per cent solution of dextrose given at the rate of about 2 cc. an hour for each kilogram of body weight, though it may be given at a much more rapid rate. The calcium is given with the dextrose, about 15 grains (1 Gm.) per thousand cubic centimeters of dextrose. Venoclysis is not administered in cases of marked edema or marked kidney destruction but is given in almost all cases of dehydration from any toxic condition, vomiting, or the like. It supplies fluid and nourishment when the intestinal tract fails to absorb. The stomach content at different times has been analyzed during this administration. It may be acid or it may be alkaline, but neither of these conditions has played a great part in the treatment.

DR. ALEXIS F. HARTMANN, St. Louis: I don't believe Dr. Helmick really wanted to give the impression that one should never give fluids intraperitoneally but rather that one should be careful about the time and the type of fluids to be given. His experience with peritoneal irritation and slow absorption has been the experience of others, particularly when dextrose solution has been used. Such a reaction has been so general that a number of workers have attempted to improve the dextrose solution to avoid this effect. Grulee and Schwentker have recommended the administration of dry sterilized dextrose but, as Darrow has shown, the effect of pure dextrose administration intraperitoneally is to take out salts and water from circulating blood and to make a solution within the peritoneal cavity that is chemically similar to the blood. I have had that impression for some time and therefore have attempted to make the injected fluid essentially similar to normal body fluids and blood plasma. I am also very careful about not injecting intraperitoneally fluid within twelve hours of a contemplated operation or when there seems a possibility of some abdominal complication. I also have found the continuous intravenous method of extreme value. I think better than just the 5 per cent dextrose solution, which, after all, affords only water and some food, which is also glycogenic in its action, is the mixture of equal parts of 10 per cent dextrose solution and lactate Ringer's solution, which also supplies the chemicals that may be necessary to help restore chemical changes.

SOME PHYSIOLOGIC CHANGES DURING HYPERPYREXIA INDUCED BY PHYSICAL MEANS

WILLIAM BIERMAN, M.D.

AND

ELLA H. FISHBERG, M.D.

NEW YORK

Forty-six years ago Dr. William H. Welch wrote: "Enlightened physicians have held the opinion that fever is a process which aids in the elimination or destruction of injurious substances which gain access to the body. The doctrine of evolution indicates that a process which characterizes the reaction of all warm blooded animals against the invasion of harmful substances has not been developed to so wide an extent and is not retained with such pertinacity without subserving some useful purpose."¹ Recent advances in the application of fever as a therapeutic agent have tended to substantiate the correctness of these ideas.

The treatment of a large series of cases by substantial elevation of body temperature within a short period of time offered us a unique opportunity for the study of the physiologic changes in the body induced in response to high temperatures. These observations are of practical value, as they permit us to rationalize this therapy on the basis of the physiologic changes which it produces and also because they may throw some light on the purposefulness of fever when it occurs in response to some insult to the body. Our observations were made on individuals suffering from a great variety of diseases. They were exposed to short-wave radiation of about 30 meters wavelength. This caused their systemic temperatures to become elevated to about 104 to 107 F. within a period varying from one to one and a half hours. This temperature elevation was then maintained for periods varying from three to six hours by trans-

From the Departments of Physical Therapy and Biological Chemistry, Beth Israel Hospital.

Read before the Section on Pathology and Physiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

ferring the patient to a bed covered with a hood containing carbon filament lamps.

In this presentation it is not our purpose to discuss in detail the changes occurring during hyperpyrexia but rather to make note of some of the summarized facts that we have observed. A more critical analysis of these changes is available in the papers that have been and are soon to be published by other workers and by ourselves.

When heat producing physical energy is applied to the body in a quantity sufficient to overcome its thermoregulatory mechanism as evidenced by a rise in the temperature of the rectum, the body makes an added effort to increase its dissipation of heat. Sweating occurs. The skin surface temperature rises promptly. The skin surface temperature gradient that ordinarily exists (the temperature of the skin covering the fingers, the lower extremities and particularly that of the toes being several degrees lower than that of the torso) is eliminated, so that the various portions of the skin surface of the body reach a more or less common temperature level. This level is lower than the temperature occurring in the interior of the body even when the temperature of the surrounding air is much higher. In the fever produced endogenously, as in response to the injection of typhoid vaccine intravenously, the temperature of the skin surface of the extremities does not rise until after the systemic temperature has become markedly elevated. Subsequently the skin surface temperature rises and its gradient disappears. Bazett noted that "while on exposure to heat there is therefore evidence of diminished peripheral resistance in the skin area, in fever, particularly during the stage when the temperature is rising, the skin appears pale, the veins are constricted and vasoconstriction in this area is indicated by a temporary failure to increase heat loss in spite of the rise in body temperature."²

Because we seriously interfered with the thermoregulation of the body and produced temperatures that with further slight additions might prove dangerous, we realized the necessity for making constant observations of the systemic temperature. We found that a knowledge of the rectal temperature as indicated by an automatic registering thermometer was a sufficiently accurate guide for this purpose. When, however, we employed a technic for the differentially increased heating of the pelvic tissues (as in the treatment of gonorrhea)³ we could no longer rely on the rectal temperature as an index of body temperature. We then followed the temperature in the mouth even though we frequently noted that the temperature of this area did not bear an exact relationship to that in the rectum. As a rule it averaged about 0.7 degree F. lower than the rectal temperature. Occasionally it was higher, or the same, or more than 2 degrees F. lower.

The velocity of the blood flow becomes markedly accelerated. On one occasion we have observed an increase of more than 400 per cent.⁴ This acceleration may be accounted for by the changes in the pulse rate, in the blood pressure, and in the volume and viscosity of the blood.

The pulse rate increases. In 500 observations we found that the rate of increase averaged 8.5 beats per minute for each degree Fahrenheit of temperature elevation. Bazett noted that the pulse rate varies in experimental pyrexia according to the body temperature in a manner similar to that of fever, with an increase of from eight to ten beats a minute for each degree above 98.6 F.²

Employing the common auscultatory technic, we noted that the systolic blood pressure usually shows a slight elevation followed by a gradual fall to a point below the original level. The sound associated with the diastolic pressure becomes audible at increasingly lower levels until it is heard (though frequently changed in character) when the mercury in the manometer reaches the zero level. After a period of an hour or two the diastolic sound becomes heard at higher levels, until it reaches a point slightly above the original one.

Although these patients lose large quantities of fluid through the sweat (as much as 3 or 4 liters) their weight at the end of the treatment is about the same as that at the beginning, if they are permitted to drink as much fluid as they desire. The blood volume commonly remains about the same and so does the blood viscosity.

The respiratory rate increases. Shortly there appear apneic periods, which gradually increase in their frequency and in their time duration so that occasionally no respiratory effort is visible during a period as long as one minute. Between these apneic periods there are intervals of increased rate and depth of respiration. With a reduction of systemic temperature the apneic periods become less frequent and shorter, and gradually the original type of respiratory excursions become reestablished. These changes in the character of the respiratory movements are reflected in the altered status of the oxygen and carbon dioxide content of the blood and in its increased p_{H_2} .

The number of the white blood cells in the blood changes. The leukocytes show an initial reduction in number of about 25 to 30 per cent occurring during the first and second hour following the inauguration of hyperpyrexia. This is constantly followed by a leukocytosis the maximum of which, amounting to about 80 per cent above the initial figure, occurs from about the sixth to the ninth hour. These variations are due mainly to changes in the total number of the neutrophils, of which the staff neutrophils show the greatest increase. These changes together with the appearance of immature forms (myelocytes, metamyelocytes, premyelocytes and myeloblasts) indicate a stimulation of the bone marrow. At a later stage the monocytes increase in number and also the lymphocytes. Repeated stimulation by heat is followed by a reduction in the leukocyte response.⁵

Observations of the rate of sedimentation of the erythrocytes when this is high show a fall in the rate as a result of temperature elevation.

The reaction, the osmotic pressure and the volume relationships of the body fluid are closely dependent on properly regulated acid-base equilibrium. Hence the study of the regulatory mechanisms for the preservation of acid-base equilibrium during heavy sweating furnishes insight into the underlying mechanisms that regulate many normal physiologic processes. The

changes to be recorded take place within a comparatively short time, so that one can study the factors regulating the acid-base balance without the interfering effects of the intake of food and the loss of catabolites in the feces. More important, one is enabled to watch the compensatory mechanisms whereby the loss of fixed base is reduced to a minimum at a time when the body fluids are undergoing marked changes. Since the patients treated in this investigation suffered from such varied pathologic conditions as dementia paralytica, tabes, acute gonorrhea, arthritis, scleroderma and psoriasis, we feel justified in interpreting the results that remain consistent throughout the investigation as fairly independent of the specific pathologic condition of the patient.

The regulating factor in the mechanism of adjustment to high temperature is naturally the very heavy excretion of sweat, the excretion of urine being below normal during this period. There is an enormous loss of body fluid through sweat, which in fact almost equals the entire blood volume. It is known that miners during work can lose as much as 3,000 cc. of body fluid an hour, and Dr. Dill informs us that during his investigations in the desert of Arizona his subjects lost as much as 5 liters an hour.⁶ During exertion and at high temperatures the lack of balance between the fixed base and the acid catabolites is augmented, and some regulatory mechanism is essential if the fixed base depots of the body are not to be drained. The base economy factor of the skin will depend on its ability to produce a fluid of lower p_H than the plasma, which acts as the carrier of catabolic products. There has been a long controversy as to the reaction of the sweat, which has only lately been settled by the introduction of the electrometric method of p_H determination. As early as 1833 Thénard reported that the sweat is definitely acid.⁷ It is known that athletes complain of stinging sweat. Marchionini⁸ showed that the divergence of the results obtained previously was due principally to the admixture of apocrine sweat, which is distinctly alkaline. This apocrine sweat is secreted by special glands in the axilla and the genitoperineal region and is very rich in odoriferous substances and cell content. During heavy sweating the proportion of this type of sweat becomes very small and results are obtained which more accurately measure the true p_H of the exocrine sweat secreted all over the body as a result of exertion and high temperature. In our cases the p_H of the sweat was determined by the hydrogen electrode method and varied between 4 and 5.

At a range of p_H as low as this, several important changes come into play. The acid substances are carried for excretion bound in the plasma and consist of carbonates, phosphates, sulphates, chlorides, the salts of organic acids and proteinates. All of these appear in the sweat except the carbonates and proteinates. The skin is impermeable to proteinates, while at a low p_H carbonates as such are practically nonexistent. Thus a wasteful expenditure of base for a catabolite that can be excreted practically base free through the lungs is avoided. This is analogous to the mechanism operating in acid urines. Thus the carbonates and proteins do not enter the sweat but remain in the plasma and exert their function in stabilizing the reaction of the blood.

The presence in the sweat of an acid that would be ionized to only a relatively low degree would allow of the excretion of a large amount of acid catabolite without undue strain on the fixed base of the body. Such an acid we found in lactic acid, which at the p_H of sweat is about 50 per cent ionized. It is peculiar that the presence of lactic acid in the sweat is scarcely mentioned in the literature. Liebermann in 1880 stated that, in patients suffering from puerperal fever, lactic acid is found in the sweat.⁹ Snapper found quantities of lactic acid of over 1 Gm. in the shirts of football players after the Olympic games.¹⁰ When it is considered that the shirts covered only a portion of the body it can be seen that the actual quantity of lactic acid must have been much higher.

In addition to its base-saving properties, lactic acid can act as a powerful buffer. It is present in the sweat in a concentration of from 250 to 350 mg. per hundred cubic centimeters. Since the chloride ion content of the plasma is about 0.35 per cent and the lactic acid 0.01 per cent it is evident that the chloride content of the plasma is about equal to that of the sweat, while the lactic acid is twenty times higher in the sweat than in the plasma. Hence the skin functions simply as an ultrafilter with regard to the chloride, while it can concentrate the lactic acid to higher amounts. It is significant that just those constituents which are excreted by the kidney at practically the same concentration as in the plasma are also excreted in the same ratio in the sweat; namely, chloride, sodium and calcium.

If a solution of weak lactic acid is titrated with its equivalent of sodium hydroxide at 37.5 C., it is found¹¹ that the p_H at the half titration point of the solution is 3.94 and the dissociation constant is 1.23×10^{-4} . Hence at the p_H of sweat, lactic acid is half dissociated. It can be excreted in an un-ionized form resulting in the sparing of 15 units of tenth normal base per hundred cubic centimeters. The absolute sparing of base is large, in view of the fact that when one is dealing with approximately 3,000 cc. of fluid, the proportion of equal parts of lactic acid and its alkali salt is the condition at which the buffer mechanism is at a maximum. This lactic acid buffer system in the sweat is analogous to the protein buffer system in the blood and the phosphate buffer system in the urine. The buffer value of the sweat is approximately that of a two hundredth-normal solution of a buffer acid whose dissociation constant equals 10^{-4} . The actual stimulus to the secretion of sweat is in dispute. It seems possible that the lactic acid formed at high temperatures and during exertion may be the actual substance initiating the process and that the lowered p_H is necessary for the proper functioning of the gland. Some mention should be made at this point of the phylogenetic homology between the mammary glands and the sweat glands.

The formation of lactic acid in the blood results in a lowering of the carbon dioxide content to levels of 30 or 25 volumes per cent, in contrast to the normal 50 or 60 volumes per cent. The stimulatory effect of the free carbon dioxide on the respiratory center soon results in a blowing off of more carbon dioxide and the patients are found to manifest extreme alkalosis,

the p_H of the blood reaching levels as high as or higher than any we have seen in a general hospital service. They approach 7.6, which is the highest value actually recorded in the literature. The low carbon dioxide tension results in a compensatory migration of the chloride from the cells into the serum in order to restore the normal values of the electrolyte distribution in accord with the Donnan equilibrium with consequent maintenance of normal osmolar relationships. The extreme loss of chloride resulting from heavy sweating naturally diminishes the chloride in whole blood, but the migration of the chloride from cells to serum results in changed distribution ratio.

The heavy sweating, by removing the chloride, results in a urine that is extremely poor in chlorides, the concentration in the urine not exceeding for the twelve hours after treatment one fourth of the content of the corresponding twelve hours before treatment.

The gastric juice shows a similar loss of chloride with a practically total cessation of secretion of free hydrochloric acid. The values of the p_H after a test meal scarcely deviates at the height of digestion from the values recorded before the meal. Certain English physiologists have shown that gastric acidity is proportional to the amount of free carbonic acid actually circulating in the blood.¹² Our results are in accord with these observations, since the increased breathing drives off carbon dioxide and the higher temperature greatly lessens its solubility, so that the lowered carbon dioxide results in a great lessening of the secretion of acid in the stomach.

The patient at a higher temperature shows a great increase in hemoglobin in response to the heightened oxygen demand. Our patients showed an increase in oxygen combining capacity from a normal of approximately 19 volumes per cent to 23 volumes per cent, which was in accord with the increased hemoglobin. In spite of this increase in the actual oxygen carrying factor of the blood, the percentage of saturation was actually lower. The difference in oxygen saturation between the venous and arterial blood was extremely small.

Because of its therapeutic significance, the effect of temperature elevation on the bacterial invaders of the human organism becomes of interest. It appears possible to exert a direct thermostatic effect on the bacteria like the gonococcus within the human body. We have on several occasions achieved a complete eradication of this organism within the female pelvis by creating a systemic hyperpyrexia plus higher local pelvic heating, to temperatures of about 110 F. which were maintained from three to four hours.¹³

Rabbits that have been immunized against staphylococci, streptococci and *Micrococcus catarrhalis* and diphtheroid bacilli showed a temporary diminution of the complement fixing antibody titer of their blood as a result of hyperpyrexia produced by physical means.¹⁴ We have also observed a reduction in the complement fixing titer in the serum of individuals suffering from gonorrhea (with positive complement fixation in the blood serum) as a result of the administration of hyperpyrexia.

SUMMARY

Observations have been made of some changes occurring in the body as a result of the elevation of its temperature by physical means. These observations included changes in the skin surface temperature, relationship between the mouth and rectal temperatures, velocity of blood flow, pulse rate, blood pressure, blood volume, blood viscosity, respiratory excursions, number of white blood cells, erythrocytic sedimentation rate, chemistry of the sweat, blood, urine, gastric contents, and the serologic reactions of the blood.

THE TREATMENT OF CHRONIC RHEUMATOID ARTHRITIS WITH STREPTOCOCCUS VACCINE

ON THE BASIS OF SKIN SENSITIVITY

CHARLES W. WAINWRIGHT, M.D.

BALTIMORE

The relation of streptococci and streptococcal infection to chronic rheumatoid arthritis remains in an uncertain and far from established position in spite of the many diligent investigations pursued during the past decade. Not only do students of the disease differ regarding the interpretation of experimental results but the results themselves lack uniformity. If a relationship exists, it might do so in one of three ways: 1. The joint lesions may be the result of the localization of streptococci circulating in the blood stream. 2. The joint lesions may be due to toxins liberated from some focus of streptococcal infection elsewhere in the body. 3. The joint reactions may be allergic in nature and represent hypersensitivity of the joint tissues to streptococci, resulting from low grade infections or from the persistence of foci of infection in the body.

If the first relation obtains, then the nature of the joint change and the method of its production are easily understood, for the condition is a metastatic infection. If the second, then a high degree of specificity is implied. If the third, then an equally high degree of specificity exists, or else one must assume with Clawson and Wetherby¹ that there is specificity for a species rather than for a strain. If the joint changes are regarded as allergic it is at times difficult to explain just how the contact of antigen with antibody comes about in the allergic joint.

The announcement by Cecil, Nicholls and Stainsby² in 1929 that they had isolated an atypical hemolytic streptococcus from the blood stream and joints of over two thirds of their patients with chronic rheumatoid arthritis immediately aroused great interest. Not only was the percentage of their positive cultures far larger than that obtained by previous investigators, but the report was particularly noteworthy since the organism isolated was hemolytic. The ability of their "typical strain" to hemolyze blood was at variance with the cultural characteristics of the organisms previously

isolated by Moon and Edwards,³ Richards,⁴ Hadjopoulos and Burbank⁵ and others. These investigators had reported finding *Streptococcus viridans* in blood cultures, although in only a small number of cases. Cecil, Nicholls and Stainsby were able, by the intravenous injection into rabbits of their "typical" hemolytic streptococcus, to produce an arthritis analogous to rheumatoid arthritis in human beings, without associated visceral lesions, and to recover the organism from the blood stream and joints of their inoculated animals.

The results of Cecil and his co-workers have been confirmed by some investigators and denied by others.

TABLE 1.—Results of Agglutination Tests with Strains of Hemolytic Streptococci

	Total Number of Cases	Total Positive Agglutinations	AB ₁₂		NY ₆	
			Living Antigens	Heat Killed	Living Antigens	Heat Killed
Chronic rheumatoid arthritis.....	51	46	41	39	42	39

For instance, Klugh⁶ was able to isolate a streptococcus in an even larger proportion of cases, namely 72 per cent, Gray and Gowen⁷ in 58 per cent, and Wetherby and Clawson¹ in 50 per cent. In these reports the organism is classified as a *Streptococcus viridans*. On the other hand, Dawson, Olmstead and Boots⁸ were able to recover a streptococcus from only 2.5 per cent of their cases, and Nye and Waxelbaum⁹ obtained no streptococci in any of their cases of either acute or chronic infectious arthritis. Lichtman and Gross¹⁰ grew streptococci from only 9 per cent of their series and considered this percentage no greater than that of the "transient streptococcemias found in the routine blood culture work of a general hospital."

Although the lack of uniformity in the results obtained from blood cultures is striking, the presence of serum agglutinins for hemolytic streptococci in a very large percentage of cases of rheumatoid arthritis has been reported by numerous observers. Dawson, Olmstead and Boots¹¹ found that 67 per cent of 157 cases possessed this property in their serums to a dilution varying from 1:20 to 1:2,560 or higher. Nicholls and Stainsby¹² found streptococcus agglutinins for their "typical strains" present in the serum of practically all patients with chronic infectious arthritis. Keefer, Myers and Oppel¹³ found that 54.5 per cent

of their patients with rheumatoid arthritis showed blood serum agglutinins for the four strains of hemolytic streptococci used.

In approaching the subject from another angle, it has been reported that patients suffering from rheumatoid arthritis show positive skin reactions to killed streptococci and their fractions in a larger percentage than do healthy persons or those suffering from some other disease. Birkhaug¹⁴ found that 47 per cent of sixty-nine cases of chronic arthritis showed marked skin reactions to both nonhemolytic and hemolytic streptococci. Myers, Keefer and Oppel¹⁵ obtained positive reactions to the nucleoprotein of a strain of *Streptococcus scarlatinae* in 70 per cent of their cases of rheumatoid arthritis, whereas 44 per cent of their control series gave positive reactions. In 32 per cent of the cases of rheumatoid arthritis the reaction was marked, whereas it was marked in but 12 per cent of the controls. Wetherby and Clawson¹ found that 91.8 per cent of their cases of chronic arthritis gave positive reactions when tested intradermally with *Streptococcus viridans* obtained from the blood of a patient with acute rheumatic fever. A positive reaction was obtained in only 49.6 per cent of their controls. They felt that the positive skin test probably indicated hypersensitiveness to the strain of streptococcus used and that the percentage of positive reactions was significantly higher in chronic arthritic patients than in a series of controls.

BLOOD CULTURES

The recovery of streptococci from the blood stream and joints of such a large percentage of cases of rheumatoid arthritis is a matter of great importance. If the observations are confirmed, the arthritis must be regarded as probably metastatic. At the Johns Hopkins Hospital I have been unable to duplicate the results of Cecil, Nicholls and Stainsby. Using essentially their technic ninety-four blood cultures in ninety-one cases

of chronic rheumatoid arthritis of the following varieties were made: seventy cultures in sixty-seven cases of rheumatoid arthritis; eight cultures in eight cases of combined arthritis; fifteen cultures in fifteen cases of atypical rheumatoid arthritis, and one culture in one case of Still's disease.

Two departures, however, were made from the technic of Cecil, Nicholls and Stainsby: 1. The blood was collected and allowed to clot in the 500 cc. Erlenmeyer flask in which the culture was to be made. Coagulation was allowed to take place with the flask in a tilted position so that the clot became adherent to the side of the flask and later could easily be broken up. After standing over night the expressed serum was

drawn off with a pipet in one manipulation. The beef heart infusion broth used as the culture medium was then transferred to the flask in which the blood had been collected and had clotted. After the addition of the broth the clot was broken up into a number of pieces by strokes of a sterile pipet. 2. Subcultures were made at ten day intervals instead of five and during the month's incubation the flask was opened only three times. The same medium was used in making the joint cultures and they were subcultured also at ten day intervals. The results of our cultures were as follows: *Streptococcus viridans* was obtained from one case of rheumatoid arthritis; diphtheroids from three cases of rheumatoid arthritis and from one case of atypical rheumatoid arthritis; staphylococci were obtained from four cases and gram-positive bacilli were obtained from three cases.

In only one instance was a streptococcus obtained, and this proved to be *Streptococcus viridans*. However, we were unable to obtain this, or any other organism when the culture was repeated. The diphtheroids occupy the usual uncertain position with regard to their significance. The staphylococci and gram-positive bacilli were considered contaminations.

Fourteen joint cultures were made in fourteen cases of rheumatoid arthritis. Twelve of these were negative, and two were contaminated with mold.

AGGLUTININ REACTIONS

We then tested the serums of fifty-one patients with rheumatoid arthritis for the presence of agglutinins for hemolytic streptococci. These tests were made with both living and heat killed antigens. The tubes were placed in the water bath at 56 C. for two hours and then transferred to the icebox, where they remained during the night and were read the following morning. The serums were tested as a routine for the presence of agglutinins for AB₁₃, a "typical" strain obtained from Cecil, Nicholls and Stainsby and for the scarlet strain NY₅. The results are shown in the accompanying tables.

In our series, forty-six patients, or 90 per cent, were found to possess agglutinins in their serum in the dilution indicated in table 2. However, the extent of the dilution in which agglutination was obtained was somewhat lower than that reported by other observers. Six per cent did not show any reaction.

SKIN REACTIONS

In order to determine the strain of streptococcus to which our cases of rheumatoid arthritis showed the maximal skin reaction, we made intradermal tests in fifty-five cases. The tests were not done for the purpose of comparing either the frequency or the intensity of skin reactions in arthritic patients with those in non-arthritic patients; therefore we have no series of controls. Our object was to determine the strain and the type of streptococcus to which the patients of our series showed the maximal skin reaction, and to use this information as a guide to vaccine treatment. We confined the tests to streptococci, not because these organisms have been so frequently recovered from the blood and joints by others, although completely missed by us, but because of the serum agglutinins for hemolytic streptococci which have been found with such constancy in these patients by all observers.

The antigens used in the tests were prepared from strains of streptococci, both hemolytic and green, obtained from foci of infection in arthritic patients; a

green strain isolated from a knee joint, later referred to as "Tschetter"; AB₁₃, the so-called typical strain obtained from Cecil, Nicholls and Stainsby, and stock laboratory strains. No tests were made with autogenous strains.

The organisms were grown in meat infusion broth for twenty-four hours. A portion of the culture was then centrifugated and the precipitated organisms were suspended in salt solution. The whole organism was used in preparing the suspension and appropriate dilutions were made, so that 0.1 cc. of the salt solution suspension contained approximately one million organisms. The suspensions were placed in the water bath at 56 C. for one hour, at the end of which time cultures were made and allowed to incubate for forty-eight hours. If the cultures remained sterile the suspensions were then ready for use. No preservative was added.

The patients were tested with from fifteen to twenty suspensions prepared in this way. One-tenth cc. of the suspension was injected intradermally on the volar surface of the forearm and the results were read from eighteen to twenty-four hours later. An area of erythema 1 cm. in diameter or larger was considered a positive reaction. In most instances the reaction was larger, varying from 1 to 5 cm. in diameter, in the center of which was an area of induration varying from 0.5 to 2 cm. in diameter in direct proportion to the size of the area of erythema. In all instances the reaction was tuberculin-like in appearance and in one instance was sufficiently violent to progress to the stage of necrosis in the central portion. In all, fifty-five cases of chronic rheumatoid arthritis were tested. The results of the tests are shown in table 3.

It will be seen that in this series all the patients gave a positive skin reaction to at least one strain of streptococcus. The number of strains to which each subject reacted varied; in but three instances did a reaction occur to only a single strain; the average number of

positive reactions was to four strains and the maximum number to twelve strains. In twenty-four instances, or 43 per cent, there was a positive reaction to one or more hemolytic strains only. No single strain predominated in causing the maximal reaction, these marked reactions being divided equally among four of the strains. In only three instances did a positive reaction occur to a viridans strain alone, and in two of these only single positive reactions were obtained. In twenty-eight cases, positive reactions were obtained with antigens of both hemolytic and green strains. In this group twenty-five showed the maximal reaction to a hemolytic strain, whereas in only three was the greatest reaction obtained with a green strain. The distribution among the hemolytic strains was not uniform, ten of the twenty-five showed the maximal reaction to Maith strain, obtained from a case of streptococcal septicaemia; NY₆, a scarlet strain and Lee, a strain obtained from a case of streptococcal septicaemia with arthritis, showed the maximal reaction in about an equal number, seven with the former and six with the latter; AB₁₃ showed the maximal reaction in two instances. Therefore, in a series of fifty-five cases, all reacting intradermally to one or more strains of the streptococci with which they were tested, forty-nine, or 90 per cent, showed the maximal reaction to a hemolytic strain, whereas only six, or 10 per cent, showed the greatest reaction to a green strain.

I shall make no attempt to interpret these results in terms of causation but wish merely to record the results. These results were useful for our purpose, since they indicated clearly to which particular strain of streptococcus, among the many used, each patient was especially sensitive.

VACCINE TREATMENT

The problem we had set ourselves was to determine the changes that would occur in the diseased joints concomitantly with a gradual reduction of skin sensitivity following the repeated injection of the antigen to which the patient was especially sensitive. An analogous situation exists in certain instances of choroiditis. This lesion is essentially inflammatory but nonspecific. It is generally thought that these choroidal lesions are in some way related to tuberculous infection, but speaking strictly one cannot say that they are tuberculous, since they possess none of the characteristic histologic features of tuberculous disease of the choroid. The assumption that they are related to tuberculosis rests chiefly on the fact that these inflammatory reactions in the choroid occur nearly always in the presence of marked tuberculin hypersensitivity as demonstrated by the intradermal test, although in most instances there is no demonstrable tuberculous disease elsewhere in the body. All that one can say definitely is that a choroiditis exists in the presence of a high grade of tuberculin hypersensitivity, and that the lesions almost always do well when the patients are desensitized to tuberculin.

Swift¹⁶ and his co-workers have shown that subcutaneous injections of killed nonhemolytic streptococci tend to sensitize rabbits, whereas similar injections given intravenously tend to make them immune. This observation decided us to use the intravenous route in giving the treatments. We were solicitous in our efforts to avoid general reactions and at the same time to minimize the possibility of the effects of foreign

protein shock reactions such as follow, for instance, the intravenous injection of typhoid vaccine.

The vaccine was prepared for each case from the strain to which the maximal skin reaction was obtained. It was a heat killed salt solution suspension of organisms, previously grown in beef infusion broth for twenty-four hours, so diluted for the initial dose that 0.5 cc. contained approximately five million heat killed organisms. No preservative was added.

An intravenous injection of 0.5 cc. was given as the initial dose and in most instances little or no constitutional reaction followed the injection. No set rule was followed in administering subsequent doses of the vaccine. The increase in dosage was gaged entirely by the patient's response. When any constitutional reaction occurred, manifested by fever, the dose was very slowly increased, keeping below the amount sufficient to produce fever. Otherwise the injections were made at four day intervals and each dose increased by 0.5 cc. If on account of a severe skin reaction it was feared that a constitutional reaction might occur, the strength of the initial dose of vaccine was decreased and the increase in dosage carefully gaged by the patient's response. In this way constitutional reactions were kept at a minimum, indeed almost entirely eliminated.

During the first period of treatment the patients were kept in the hospital, in most instances in bed, a necessary precaution in many cases on account of the severe involvement of the knee joints. No other treatment was employed except the use of salicylates and sedatives as was necessary for the alleviation of pain. The injection of vaccine was continued at four day intervals during the stay in the hospital, which was from four to eight weeks' duration. Following discharge the interval was lengthened to seven days and the patients returned to the outpatient department for treatment, except in those instances in which the involvement of the joints of the lower extremities made this impossible.

Twenty-eight cases have so far been treated for periods ranging from two months to over one year. Of this number twenty-five patients had definite chronic rheumatoid arthritis, three suffered from combined arthritis in which the rheumatoid features predominated. In all cases symptoms and signs of the disease had been present for at least six months, the average duration being approximately two years. All foci of infection had been removed and sufficient time allowed to elapse to convince us that no benefit or further benefit would follow. Under treatment, twenty-one cases, or 75 per cent, have shown evidence of definite improvement.

The improvement manifested itself by reduction of pain, reduction of soft tissue swelling and increased mobility of the joint. In joints in which bone destruction and true ankylosis had occurred, the mobility could not be increased but pain and soft tissue swelling were reduced. It has not been unusual to see fusiform swelling of the fingers decrease in size and in some instances disappear altogether. Eight patients were bedridden when treatment was begun; five of these are now out of bed and able to move about; two of the remaining three have been under treatment barely two months; the third has been treated for five months. The two under treatment only two months have shown definite improvement, whereas the one treated for five months has not been appreciably benefited. In all three cases there was extensive involvement of the knees.

¹⁶ Swift, H. F.: Pathogenesis of Rheumatic Fever, *J. Exper. Med.* 39: 497 (April) 1924.

Although constitutional reactions have been absent or minimal, the patients have rather uniformly complained of focal reactions, indicated by increased pain in the involved joints for twenty-four hours after the injections. Following this reaction the joints have been less painful. Amelioration of symptoms has appeared gradually, becoming definite usually after from three to five weeks, and from then on progressing slowly. The course of improvement has not been uniform in all cases; at times joints flare up during treatment but subside in a shorter time than is usual in the spontaneous remissions of chronic arthritis. Although improvement has not been obtained in all cases, in no instance has there been any untoward effect; nor has an aggravation of the condition resulted from the treatment.

Seven cases have failed to show any definitely favorable response. In three of these we were disappointed because in the light of the response made by other patients it seemed reasonable to anticipate improvement. Two of these, however, have been under treatment only a short time. Two of the remaining five cases gave a history of long standing joint involvement with pain as the chief symptom, whereas the inflammatory process was relatively inactive. In the remaining two cases a combined arthritis was present.

Twenty-six of the cases showing the maximal skin reaction to a hemolytic strain have been treated with hemolytic streptococcus vaccine. In nine instances the Maith strain, obtained from a case of hemolytic streptococcus septicemia, was used. In nine cases NY₆, a scarlet strain, was used; in four, AB₁₃, a "typical" strain furnished us by Cecil, Nicholls and Stainsby; in four, the Lee strain, obtained from a case of hemolytic streptococcus septicemia with acute infectious arthritis. The viridans strains used were Tschetter, isolated from a knee joint, and Waller, a stock laboratory strain from an unknown source.

During the course of treatment the skin reaction to the strain employed has uniformly diminished in intensity and frequently disappeared entirely. The agglutinating power of the patient's serum has materially increased, and those patients whose serum failed to agglutinate the organism before treatment was begun gradually developed agglutinins for the organism used in treatment. The increase in titer varied from 1:1,280 to 1:10,240 and was occasionally as high as 1:20,480. In one of the cases in which a green strain was used, agglutination was absent before treatment was given but appeared shortly after and rose gradually until it was present in a dilution of 1:10,240. In the second case no agglutination of the organism used in treatment has ever developed.

We determined the sedimentation rate of the erythrocytes in only a small number of our cases. In these few the rate decreased as improvement took place but in none did it reach normal.

COMMENT

Our efforts to recover streptococci from the blood and joints of cases of chronic rheumatoid arthritis have completely failed. In one instance a *Streptococcus viridans* was obtained but it was present for only a short time, and I feel that this must be regarded as a transient bacteremia. In reporting these results I realize that the limited number of cases does not warrant any sweeping conclusions but wish merely to record our failure to corroborate the work of those investigators who find streptococci in the blood and

joints in a large proportion of cases of rheumatoid arthritis.

On the other hand the presence of agglutinins for hemolytic streptococci in the serums of patients suffering from chronic rheumatoid arthritis seems well established. A positive reaction does not indicate of necessity a causal relationship between hemolytic streptococci and rheumatoid arthritis but it does suggest that streptococci play a rôle in the disease. Agglutination may be due to the presence of natural rather than acquired or specific agglutinins, as Dawson, Olmstead and Boots¹¹ suggest, but the frequency with which it occurs in rheumatoid arthritis is the most incriminating evidence thus far produced against the streptococcus in this disease and merits some consideration.

The presence of skin sensitivity to streptococci does not necessarily indicate that there is also joint sensitivity or general sensitivity. The objections raised by Short, Dienes and Bauer¹⁷ to the interpretation of skin reactions to autogenous vaccines, namely, that they may indicate varying irritability of the patients' skins, natural toxicity of the bacterial species or perhaps sensitization to certain bacterial groups, must be considered. However, the effect on the reactions of subsequent treatment with vaccines indicates that they do represent a specific skin sensitivity to the strain used.

I am not prepared to offer an interpretation of the changes occurring after intravenous injection of vaccine. I do not know that the diminution and disappearance of the skin reaction is a measure of desensitization or that the increase in the agglutinating power of the patient's serum is a measure of immunity. However, I do feel that the skin reaction is the most definite evidence of hypersensitiveness we could obtain and wish to cite the observations we have made and record the improvement which has taken place in the patients we have treated. I realize that any claim to specificity could be justifiably disputed and that it is not beyond the realm of possibility that the improvement brought about is the result of treatment which is nonspecific in character. We have succeeded in eliminating or at least minimizing the feature of non-specific therapy to which is commonly attributed the benefit derived from vaccine treatment. The evidence of improvement has appeared fairly early, but the long continued use of vaccine may be of further value.

SUMMARY

1. Ninety-four blood cultures in ninety-one cases of rheumatoid arthritis yielded *Streptococcus viridans* in one case, diphtheroids in four cases, staphylococci in four cases and gram-positive bacilli in three cases.
2. Fourteen joint cultures in fourteen cases of rheumatoid arthritis were negative.
3. The serums of forty-six, or 90 per cent, of fifty-one cases of rheumatoid arthritis were found to possess agglutinins for hemolytic streptococci.
4. All of fifty-five cases of rheumatoid arthritis gave positive skin reactions to one or more strains of streptococci.
5. Twenty-one of twenty-eight cases of rheumatoid arthritis have shown improvement following intravenous injections of streptococcus vaccine prepared from the strain to which the skin was most sensitive.

IS THERE A SCARLET FEVER
TOXOID?

GEORGE F. DICK, M.D.

AND

GLADYS HENRY DICK, M.D.

CHICAGO

In early studies of diphtheria toxin, it was observed that on standing the toxin undergoes spontaneous change resulting in loss of toxicity. But this loss of toxicity is not accompanied by corresponding loss in ability to neutralize diphtheria antitoxin. In elaborating his theory of immunity, Ehrlich employed the term "toxoid" to designate this nontoxic substance which is still able to bind antitoxin. The French prefer the term "anatoxin" for this substance. The change from toxin to toxoid, which takes place spontaneously in solutions of diphtheria toxin, may be hastened by addition of certain chemicals. Ramon used formaldehyde to accelerate and complete the change from diphtheria toxin to toxoid and utilized the formalized product for active immunization. He found the same method useful in obtaining toxoid from tetanus toxin. Toxoids that have lost their toxicity but retain the ability to neutralize and stimulate the production of antitoxin are satisfactory agents for active immunization against some diseases in which soluble toxins are concerned.

Scarlet fever toxin kept at icebox temperature in insoluble glass containers does not undergo spontaneous loss of toxicity comparable to the change noted in diphtheria toxin. However, attempts have been made to obtain a scarlet fever toxoid through treatment of the toxin with formaldehyde.

In this article the expression "solution of formaldehyde" is used in the sense of the U. S. Pharmacopeia to designate a solution containing not less than 37 per cent of formaldehyde gas.

Zoeller¹ studied the effect of formaldehyde on scarlet fever toxin in solutions to which he added from 0.25 to 1 per cent of a 40 per cent solution of formaldehyde before storing at 38 to 39 C. for a period of thirty days. From standardization by means of skin tests before and after treatment with formaldehyde, Zoeller determined that addition of 0.25 to 0.5 per cent solution of formaldehyde did not produce appreciable attenuation of the toxin. One per cent solution of formaldehyde caused considerable attenuation, but detoxification was not complete even when 2 per cent solution of formaldehyde was used. Sparrow and Celarek² added 0.5 per cent solution of formaldehyde and stored the preparation six weeks at 38 C. They then used this material in immunization experiments and reported 88 per cent of 143 susceptible children immunized by 3 cc. of the formalized toxin. Smith³ titrated his toxin before and after treatment with formaldehyde. Like Zoeller, Smith found marked loss of toxicity following addition of 2 per cent solution of formaldehyde and but slight detoxification in mixtures containing from 0.5 to 1.0 per cent. None of Smith's preparations were completely detoxified. Injecting 3 cc. of formalized toxin, he obtained immunity in from 52 to 56 per cent. Debré and Ramon⁴ used

0.5 per cent of a 40 per cent solution of formaldehyde and stored the preparation at from 38 to 40 C. for from one month to six weeks. In subsequent immunization experiments they found that the less toxic preparations that caused fewer reactions produced less immunization than the more toxic samples. Mureddin⁵ used a formalized mixture of scarlet fever and diphtheria toxin to which 0.4 per cent solution of formaldehyde was added before incubation at from 38 to 39 C. for only four to five days. He injected graduated doses of this mixture, totaling 3 cc. in children susceptible to both scarlet fever and diphtheria, and reported that 81 per cent developed negative skin tests, indicating immunity to both diseases. Mureddin standardized the diphtheria but not the scarlet fever toxin before and after treatment with formaldehyde. Futagi⁶ employed scarlet fever toxin to which 0.4 per cent of a 30 per cent solution of formaldehyde was added before storage at temperatures ranging from 40 to 48 C. for periods varying from seven to sixty days. With these different preparations of formalized toxin injected in four doses totaling 3.8 cc., the immunity obtained varied from 25 to 84.5 per cent, compared with 99.3 per cent following administration of 26,000 skin test doses of unmodified toxin. This author did not state the titer of the toxin after treatment with formaldehyde. Veldee⁷ of the United States Public Health Service recommends use of the acetone insoluble portion of the toxin containing broth filtrate redissolved in broth, treated with 0.4 per cent solution of formaldehyde and stored at 37 C. for about sixty days. Veldee attempts to determine the amount of residual toxin by means of skin tests on rabbits and advises the further addition of 0.05 per cent solution of formaldehyde if tests on rabbits indicate insufficient detoxification. He reported 87.3 per cent susceptibles immune on retest after three doses consisting of 0.1, 0.5 and 1 cc. of his formalized preparation.

In considering results of previously published work, it is noted that none of the authors were able completely to detoxify scarlet fever toxin, though some used as high as 2 per cent of a 40 per cent solution of formaldehyde. Zoeller and Smith determined the degree of detoxification with different amounts of formaldehyde and agree that there is comparatively little loss of toxicity following the addition of the smaller amounts of solution of formaldehyde up to 0.5 per cent. In this connection it is significant that preparations of scarlet fever toxin containing the largest amounts of formaldehyde gave the lowest percentage of immunity following injection of the formalized toxin, while the best results have been reported by authors who used less than 0.5 per cent solution of formaldehyde. This suggests that reduction in toxicity on addition of formaldehyde to scarlet fever toxin may not be due to conversion of the toxin into a true toxoid. The better results obtained with toxin treated with smaller amounts of formaldehyde might be due to the presence of larger amounts of unaltered toxin remaining in such solutions.

Apparently most investigators have been so influenced by analogy between the soluble toxins of the diphtheria bacillus and the scarlet fever hemolytic streptococcus that they have assumed the partial loss of toxicity on treatment of scarlet fever toxin with

formaldehyde was necessarily due to conversion of the toxin into toxoid. Without other basis, some have described the formalized toxin as "scarlet fever toxoid" and, in interpreting the results of immunization experiments, have ignored the possible effect of the unaltered toxin remaining in the formalized preparations. Veldee carried the analogy further in advising the addition of alum to precipitate the scarlet fever toxoid before injection.

The following experiments, begun in 1927, were undertaken to learn whether the addition of formaldehyde to scarlet fever toxin results in the formation of a scarlet fever toxoid, nontoxic but capable of binding scarlet fever antitoxin, and capable of stimulating the production of antitoxin when injected into susceptible individuals.

IMMUNIZATION EXPERIMENTS WITH FORMOLIZED TOXIN

1. One liter amounts of a broth culture filtrate containing toxin specific to scarlet fever were placed in glass stoppered Pyrex flasks. A neutral 37 per cent solution of Merck's reagent formaldehyde was added in 1, 2, 3, 4, 5, 6, 8 and 10 cc. amounts to different flasks, and to one flask no solution of formaldehyde was added. All flasks were sealed and kept in an incubator at 38 C. for a period of six weeks. At the end of this time the toxin remaining unchanged in each flask was titrated by means of skin tests on susceptible human beings compared with the results of skin tests made simultaneously on the same individuals with one standard skin test dose of scarlet fever toxin. Toxin in the flask to which no formaldehyde had been added contained 37,500 skin test doses per cubic centimeter. There was some loss of toxicity in all flasks containing formaldehyde, but detoxification was not complete in any flask. Loss of toxicity was in proportion to the amount of formaldehyde. Samples from flasks to which less than 0.5 per cent solution of formaldehyde had been added still contained more than half of the original amount of toxin. The greatest loss of toxicity occurred in the flask to which 1 per cent solution of formaldehyde had been added. Accurate standardization showed that in this flask the original toxicity of 37,500 skin test doses per cubic centimeter had been reduced to 4,000 skin test doses per cubic centimeter. This material was used in subsequent immunization experiments in a total dosage ranging from 2.675 to 13.675 cc. In control experiments 3.2 cc. of toxin from the flask containing no formaldehyde were injected in five graduated doses. Of sixty-seven susceptible young adults between the ages of 18 and 30 years in this control series, 91 per cent were immune to one skin test dose on retest two weeks after the last injection. At first the formalized toxin was injected undiluted in doses of 0.125, 0.5 and 2 cc., but when it was found that this dosage did not confer immunity in most cases the amount injected was gradually increased up to 13.675 cc. given in the following doses of undiluted material: first dose, 0.125 cc.; second dose, 0.5 cc.; third dose, 2 cc.; fourth dose, 3 cc.; fifth dose, 4 cc.; sixth dose, 4 cc.

Fifteen, or 75 per cent, of twenty persons who received the larger dosage of formalized toxin developed immunity to one skin test dose of toxin.

Before the addition of formaldehyde, the 13.675 cc. had contained 512,812.5 skin test doses of toxin; yet injection of this amount of formalized toxin conferred less immunity than injection of 119,875 skin test doses of unmodified toxin; moreover, the 13.675 cc. of formalized toxin still contained 54,700 skin test doses of unaltered toxin which might account for all of the immunity obtained.

2. In the next experiment another lot of formalized toxin was used. This toxin originally contained 40,000 skin test doses per cubic centimeter and after incubation for two months with 0.8 per cent solution of formaldehyde the toxicity was reduced to 2,000 skin test doses per cubic centimeter. Injected in five doses of 0.25, 1, 3, 3 and 3 cc., this preparation conferred immunity in 52 per cent of 75 susceptible young adults.

The total volume of 10.25 cc. had contained 410,000 skin test doses of toxin before treatment with formaldehyde and after treatment it still contained 20,500 skin test doses of unaltered toxin. In a control series of seventy-nine young adults, the untreated toxin given in five doses, totaling 2.9 cc. and containing 115,500 skin test doses, immunized 91 per cent.

This same formalized preparation was then employed in two schools, where nose and throat cultures were made on blood agar plates and all children showing hemolytic streptococci in nose or throat culture were excluded from school until immunization of the noninfected susceptibles had been completed. The 207 susceptible children between the ages of 5 and 19 years were divided into two groups. One group received the formalized toxin in the first three immunizing doses and untreated toxin in the last two doses as follows:

First dose of formalized toxin.....	0.25 cc.
Second dose of formalized toxin.....	1 cc.
Third dose of formalized toxin.....	4 cc.
Fourth dose of untreated toxin.....	0.625 cc.
Fifth dose of untreated toxin.....	2 cc.
Total	7.875 cc.

The other group received unmodified toxin of the same lot used in producing the formalized toxin in the following dosage:

First dose of untreated toxin.....	0.0125 cc.
Second dose of untreated toxin.....	0.05 cc.
Third dose of untreated toxin.....	0.2 cc.
Fourth dose of untreated toxin	0.625 cc.
Fifth dose of untreated toxin.....	2 cc.
Total	2.8875 cc.

Since this formalized toxin contained 2,000 skin test doses of unaltered toxin per cubic centimeter, the amount of unmodified toxin injected in each series was the same: 115,500 skin test doses. But in addition to the unmodified toxin injected in both groups, the first group received 199,500 skin test doses of detoxified toxin. If the detoxified portion of the formalized toxin contained toxoid capable of stimulating the production of antitoxin, the group that received 5.25 cc. of the formalized toxin in addition to the unmodified toxin might be expected to show more immunity than the second group, which received only the unmodified toxin. This was not the case. The development of immunity in the two groups was practically the same, being 95.3 per cent in the 103 children who received only the untreated toxin and 94.2 per cent in the 104 children who received the formalized toxin in addition to the unmodified toxin.

3. In the next experiment a third preparation was employed. This toxin also originally contained 40,000 skin test doses per cubic centimeter and its toxicity was reduced to 4,000 skin test doses per cubic centimeter after treatment with formaldehyde. It was used in two orphanages after nose and throat cultures as well as skin tests had been made on every one and all those infected with hemolytic streptococci had been quarantined from noninfected susceptibles. In these institutions there were 118 noninfected susceptibles. To half of these in each institution the formalized toxin was given in the doses shown in table 1. In the other half, untreated toxin of the same lot used to produce the formalized toxin was given in the doses shown in table 2.

If the 94,500 skin test doses of toxin that had been detoxified in the 2.625 cc. of the formalized toxin had been converted into toxoid, the group that received the formalized toxin should have shown considerably more immunity on retest than those who received only 0.2625 cc. of the untreated toxin. Two weeks after the third dose was given, retests were made. These showed practically the same degree of immunity in the two groups. Of the fifty-nine children who received the formalized preparation, twenty-five, or 42 per cent, were immune to one skin test dose of toxin, and twenty-four, or 40.6 per cent, were immune in the other group.

Immunization in both groups was continued by injection of 25,000 and 100,000 skin test doses of the untreated toxin. Following this, skin tests showed 97 per cent immune.

Results of these experiments indicate that, although incubation with 0.8 to 1 per cent of a 37 per cent solution of formaldehyde may cause detoxification of as much as 95 per cent of the toxin in a solution of scarlet fever toxin, no evidence is found that the detoxified portion possesses antigenic properties. Such immunity as resulted from injection of the formalized

toxin could be explained by the considerable amounts of unaltered toxin remaining in the solution.

On publication of Veldee's work from the United States Public Health Service, arrangements were made to use formalized scarlet fever toxin prepared by Veldee in the National Institute of Health. Veldee started with a stronger toxin than we had used and it was thought the better results which he reported might be due to the fact that he had used a stronger toxin for treatment with formaldehyde.

When received, the material was labeled "Scarlet Fever Toxoid." The label stated that its original toxicity had been 150,000 skin test doses per cubic centimeter and that after the addition of 0.35 per cent solution of formaldehyde and storage at 37 C. for eighty-eight days the toxicity had been reduced to 500

that scarlet fever toxin is precipitated by alum. To determine whether it would be advisable to add alum, the following experiment was made.

EXPERIMENTS TO LEARN THE EFFECT OF ALUM ON SCARLET FEVER TOXIN

Following the method described by Leonard and Holm⁸ for diphtheria toxin and toxoid, 5 cc. of a 10 per cent solution of sodium alum was added to 50 cc. of an undiluted scarlet fever skin test toxin containing 15,000 skin test doses per cubic centimeter. The mixture was placed in the icebox for three hours, centrifugated and the supernatant fluid discarded. The precipitate was washed twice in 25 cc. distilled water, and treated with 2.4 per cent disodium acid phosphate. After centrifugation the remaining precipitate was dissolved in 5 cc. of 5 per cent sodium citrate solution and diluted to 50 cc. with 0.3 per cent sodium chloride containing 0.4 per cent phenol. This solution was sterilized by passage through a Berkefeld W porcelain filter.

The amount of toxin in the solution of the alum precipitate was determined by means of skin tests on susceptible human beings compared with the results of tests made on the same individuals with one standard skin test dose of toxin, with the results shown in table 3.

Diphtheria toxin was treated in the same way. Tests for the presence of diphtheria toxin in the redissolved precipitate were made by injection subcutaneously in 250 Gm. guinea-pigs.

One cubic centimeter of a 1:100 dilution of the original toxin caused a local reaction but did not kill the pig. One cubic centimeter of a 1:10 dilution killed a pig on the second day.

One cubic centimeter of a 1:50 dilution of the redissolved alum precipitate caused a local reaction. One and eight-tenths cubic centimeter of a 1:5 dilution killed a pig on the second day.

In this experiment no evidence of toxin was found in the alum precipitate from scarlet fever toxin, but toxin was demonstrated in the alum precipitate from diphtheria toxin. In view of these results it was decided to use the "scarlet fever toxoid" without the addition of alum.

IMMUNIZATION EXPERIMENTS WITH VELDEE'S "SCARLET FEVER TOXOID"

In a control group of seventy-eight persons susceptible to scarlet fever as shown by positive skin reactions to one skin test dose of scarlet fever toxin, five graduated doses of an unmodified scarlet fever toxin containing 45,000 skin test doses per cubic centimeter were injected at weekly intervals. The toxin in the smaller doses was diluted with physiologic solution of sodium chloride to facilitate accurate dosage. Retests made

skin test doses per cubic centimeter. Two methods of immunization were recommended on the label, the first consisting of injection of 0.1, 0.5 and 1 cc. at intervals of three weeks and the second consisting of the addition of sufficient potassium alum to make the final solution contain 0.5 per cent alum and administration of two doses of 0.25 and 0.5 cc. measured before addition of the alum.

It is known that alum precipitates diphtheria toxin, but there was no evidence in the literature to indicate

two weeks after injection of the fifth dose showed seventy-seven persons, or 98.6 per cent, immune to one skin test dose of toxin.

At the same time in the same institution the "scarlet fever toxoid" was injected in a group of forty-one susceptible persons in three doses of 0.1, 0.5 and 1 cc. at intervals of three weeks, as Veldee suggests. Retests were made in this group one month after the last dose was injected. Thirty-five were retested, the others having left the institution or died in the interval of two and a half months. Of the thirty-five retested, fourteen, or 40 per cent, were immune to one skin test dose of toxin. In most of the others the skin reaction was modified though still positive.

In administering the "toxoid" no reactions were expected, because the label stated that it contained only 500 skin test doses of residual toxin per cubic centimeter. However, the reactions observed following the first dose of 0.1 cc. were such as to suggest that the patients had received considerably more than the fifty skin test doses of unchanged toxin indicated by the label.

Veldee used rabbits to determine how much unaltered toxin remained in solution following treatment with formaldehyde. Compared with human beings the rabbit is insusceptible to scarlet fever, as shown by the fact that the majority of rabbits show negative skin reactions to the standard skin test dose of toxin, which

TABLE 5.—Comparative Results with Untreated Toxin and with "Scarlet Fever Toxoid" Prepared by Veldee

gives positive reactions in susceptible human beings; by the fact that the scarlet fever rash is not produced in rabbits by intravenous injection of large amounts of toxin or by inoculation with living cultures of the scarlet fever streptococcus; also by the fact that scarlet fever toxin is inhibited by normal rabbit serum mixed with it in vitro before it is injected intradermally in susceptible human beings. This comparative insusceptibility makes the rabbit an unsuitable subject for accurate standardization of either scarlet fever toxin or scarlet fever antitoxin, since the latter is merely titration of free toxin left in the toxin-antitoxin mixture.

STANDARDIZATION OF UNMODIFIED TOXIN REMAINING IN VELDEE'S "TOXOID"

The amount of unchanged toxin remaining in the Veldee preparation was therefore standardized by means of skin tests on one arm of susceptible human beings compared with the reactions produced by injection of one standard skin test dose of toxin on the other arm. Results of tests made with 0.1 cc. of a 1:800 dilution of the "toxoid" are shown in table 4.

By this means it was learned that the preparation which as the result of tests on rabbits was labeled as containing 500 skin test doses of toxin actually contained 8,000 skin test doses of unchanged toxin per cubic centimeter.

Thus it was apparent that in giving the doses of 0.1, 0.5 and 1 cc. there had been injected along with the

detoxified toxin 800, 4,000 and 8,000 skin test doses of unaltered toxin. To learn how much of the immunity obtained was attributable to the unmodified toxin present in the "toxoid," a group of forty-two young adults who had received the first three doses of untreated toxin usually given in routine immunization were retested before the fourth and fifth doses were

given. It was found that sixteen, or 36.7 per cent, were immune to one skin test dose of toxin. The total amount of toxin given in this group was somewhat less than the total amount of unmodified toxin injected in the three doses of the formalized preparation. If the detoxified portion of the formalized preparation had possessed antigenic properties, the group receiving the formalized toxin should have shown as much immunity as those who received five doses of untreated toxin, instead of less than half that immunity. Also the group that received the formalized toxin should have shown considerably more immunity than those who received only three doses of untreated toxin; yet the immunity in the two groups was practically the same, indicating that the detoxified portion of the formalized preparation had little if any antigenic action.

That failure to develop more immunity in the "toxoid" group was not due to any peculiarity of the individuals composing the group was learned by injecting the fourth and fifth doses of untreated toxin, after which retests showed all but one, or 97.1 per cent, com-

TABLE 7.—Failure of Detoxified Toxin to Bind Scarlet Fever Antitoxin

pletely immunized. Thus the children in the "toxoid" group had received the full amount of unmodified toxin given in the control group before their immunity was comparable to that in the control group.

Having failed to demonstrate the existence of a "toxoid" in the formalized scarlet fever toxin by means of immunization experiments in susceptible human beings, we attempted to demonstrate a nontoxic substance capable of binding scarlet fever antitoxin in Veldee's formalized scarlet fever toxin.

EXPERIMENTS TO DETERMINE WHETHER THE DETOXIFIED PORTION OF FORMOLIZED TOXIN IS ABLE TO BIND SCARLET FEVER ANTITOXIN

Some of Veldee's formolized toxin used in the preceding experiment was diluted 1:200 so that each 0.1 cc. contained four skin test doses of unchanged toxin and seventy-one skin test doses of detoxified toxin. This was mixed with an equal volume of scarlet fever antitoxin diluted so that each 0.1 cc. contained sufficient antitoxin to neutralize ten skin test doses of toxin. The "toxoid"-antitoxin mixture contained in each 0.1 cc. two skin test doses of unmodified toxin, 35.5 skin test doses of detoxified toxin, and enough antitoxin to neutralize five skin test doses of toxin. This mixture was allowed to stand in the incubator two hours, and to half of it sufficient untreated toxin was added to make the toxin content in each 0.1 cc. five skin test doses, or the full amount necessary to bind the antitoxin. As a control the same untreated toxin used in the mixtures described, containing 20,000 skin test doses per cubic centimeter, was diluted 1:500 so that it contained four skin test doses in each 0.1 cc. and combined with antitoxin and additional toxin in the same proportions used in the "toxoid" experiment except that, instead of three additional skin test doses of toxin in each 0.1 cc., four additional skin test doses were added, or one more skin test dose of toxin than the amount of antitoxin used should be able to neutralize.

"Toxoid," toxin and antitoxin control mixtures were also prepared, physiologic solution of sodium chloride being substituted for the "toxoid," toxin or antitoxin in the mixtures. After it had stood in the icebox overnight, 0.1 cc. of each solution was injected intradermally in persons susceptible to scarlet fever.

From the results in table 6 it is apparent that, if one more skin test dose of toxin is added to the toxin-antitoxin mixture than the antitoxin present can hold in combination, the excess toxin is manifested in a positive skin reaction.

If the 37.5 skin test doses of detoxified toxin in 0.1 cc. of the "toxoid"-antitoxin mixture had had combining power equivalent to one skin test dose of unaltered toxin, the skin reactions would have been positive with the "toxoid"-antitoxin mixture to which toxin was added after incubation as they were in the corresponding mixture in which untreated toxin was used instead of "toxoid." This was not the case.

RABBIT IMMUNIZATION EXPERIMENTS

Experiments were made in immunization of rabbits by injecting intravenously in three rabbits the formolized toxin prepared by Veldee. Untreated scarlet fever toxin was injected in a second group of three rabbits, and sterile, uninoculated broth in three rabbits. A dilution was made of the untreated toxin, which contained in each cubic centimeter an amount of toxin exactly equal to the unaltered toxin remaining in each cubic centimeter of the undiluted formolized preparation. Before injection, all rabbits showed positive reactions to fifty skin test doses of toxin injected intradermally on the ear. The intravenous injections were made at intervals of two weeks, beginning with 1 cc. and increasing to 20 cc. Before each dose the skin test was repeated. The rabbits in the control group injected with broth continued to show positive reactions. The rabbits injected with the diluted, untreated toxin developed negative skin reactions as early as those which received the undiluted formolized toxin.

Thus these experiments failed to demonstrate any antigenic substance in the formolized toxin other than the unaltered toxin remaining in it.

CONCLUSIONS

1. Scarlet fever toxin is partially but not completely detoxified by treatment with solution of formaldehyde up to 1 per cent. The presence of unaltered toxin in the formolized preparation is sufficient to account for the immunity obtained.

2. No evidence now available justifies the assumption that there is a scarlet fever toxoid analogous to diphtheria toxoid.

3. Alum precipitates diphtheria toxin and the toxin may be demonstrated in the precipitate; but the redissolved alum precipitate from scarlet fever toxin showed no evidence of the presence of toxin.

4. The rabbit is not a suitable subject for standardization of scarlet fever toxin.

5. Since the detoxified portion of formolized scarlet fever toxin is not antigenic, it is inferior to unmodified toxin as an immunizing agent because of the unnecessary amount of useless foreign protein which it contains.

THE SYNDROME OF HYPERTONIC AND ATONIC COLOPATHY

FRED H. KRUSE, M.D.

SAN FRANCISCO

Colitis is a much used and abused term, and most certainly the medical profession should limit its application to include only inflammatory states of the large bowel. These inflammations, from simple catarrhal to chronic ulcerative colitis, as well as related conditions producing definite pathologic lesions, have been well demonstrated, and their causative agents have been determined, ranging from chemical poisons, certain deficiency states, as noted in pellagra and sprue, protozoan infestations and, above all, bacterial infections.

A diagnosis establishing a case of acute or chronic bowel disorder, in the foregoing category, as an actual colitis affords some satisfaction in classifying the disorder and some comfort in the knowledge that one may proceed with therapy more or less promising and universally recognized. There still remain chronic constipation and intermittent diarrhea to plague, confound and divide the profession. These complaints represent by far the greater proportion of chronic bowel disorders that occur without any evidence of definite pathologic lesions of the mucous membrane.

ETIOLOGY

As in migraine, so in the more chronic colopathies characterized by constipation and intermittent diarrhetic episodes, the cause of the condition has been assigned, on the one hand, to constitutional and functional factors and, on the other, to local irritative lesions or more general metabolic disorders. The latter conception would seek out and eliminate all neighborhood irritative factors that may arise intermittently, such as local disease in the rectum, pelvis or abdomen. It would correct also those presenting a general constitutional effect, such as certain food intolerances due to intestinal allergy or to an unfavorable intestinal flora-producing fermentation and congestion.

It must be admitted that adjacent inflammatory or irritative foci, namely, chronic appendicitis, disease of the gallbladder and pelvic disorders, and local rectal lesions (rectal ulcers, retention crypts, fistulas and hemorrhoids), as well as those other disturbances already noted, may produce secondary bowel disorders. Still the clinician, as a rule, is disappointed in the results

Read before the Section on Practice of Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

obtained by treatment of these conditions alone, and by necessity of failure to gain much or even any improvement in his patient's symptoms has come to realize that the fundamental problem has not been solved. Therefore more attention has been paid to the functional elements, which has led to a study and analysis of the form of the colon, as exemplified by variations in length, loops, tone and position, and to the motor activity and function of the disturbed bowel, in order to understand the factors that affect and control it.

As in migraine, students of the more chronic colopathies, described later in more detail, recognize a probable congenitofunctional origin, since the causes of chief influence are partly congenital but inherently functional, and are manifested by certain psychic and autonomic disturbances of the nervous system.

COLON FORM AND FUNCTION

This critical study of the large bowel has led to knowledge of a usual or normal colon form; to redundancies or increased lengths with various loopings in different portions; to hypertrophy of sections of the bowel wall with dilatation, as in megacolon, and to what Larimore¹ calls "hyperrotation" of the cecum, or low descent. Any or all of these, with the possible exception of megacolon (which is typically atonic), may give rise to either diarrhea or constipation at various periods.

Further investigation of motor function has demonstrated phases of hypotonicity and hypertonicity in the colon leading to the classification, on the one hand, of atonic constipation and, on the other hand, of spastic constipation and mucous colitis. While apparently opposite conditions, they are undoubtedly fundamentally related; in all there is evidence of a constitutional and functional disturbance or imbalance of the autonomic nervous system, even though there is congenital variation in the form of the colon.

With a history of constipation and roentgen evidence of a relaxed or apparently dilated colon, usually a diagnosis of atonic constipation is made, and the physician has been content to treat the condition as such, in the accepted manner, with a bulky diet containing roughage, with various laxatives or other form of bowel stimulation and, much too frequently, with prolonged rectal and high colonic irrigations. In a surprisingly large proportion of such cases, mucous outpouring and diarrhea ensue, so that from an atonic regulatory regimen one must reverse to that of hypertonicity and irritability, because of evidence of most of the characteristics of irritable colon and mucous colitis.

Atonic as well as hypertonic states exist and can be demonstrated roentgenologically. Either may produce obstinate constipation, but it has been my observation that the two are more likely to occur at different times in the same individual than to characterize uniformly the bowel habitus of one person as against that of another. Any of the bowel-form types noted may show irritability, which is characteristic of hypertonia, or may be apparently atonic.

ATONIA

However, there is a uniform tendency for hypertonicity to be more apparent in shorter and more normal forms, whereas atonic loops and states appear more frequently as the bowel becomes more redundant. Finally, the only consistently atonic cases are found in

the more serious redundancies, which may lead to volvulus, and in megacolon, where there is a local organic thickening or hypertrophy of the bowel wall in the part affected, as well as a congenital overaction of the sympathetic nervous system leading to dilatation. After many such cases have been observed, evidence accumulates that long before bowel "paralysis" or atonia becomes persistent, increasing degrees of decompensation or stretching appear, as the result of gradual development of autonomic nerve imbalance.

I myself have felt for a long time that the designation "atonic form" of constipation is misleading. By following the barium meal down the bowel with the fluoroscope and later supplementing these observations with the barium enema, I have learned that constipation due to uniform relaxation of the colon tube is rarely seen and possibly never exists throughout the whole length of the bowel at one time. It is conceded that there are regions of relaxation as there are of spasticity at times, and these vary. But it is the incoordination of muscular motor function rather than its paralysis or absence that is at the base of all constipation, except in the definitely mechanical obstructive types. One often sees relaxed, distended loops of bowel in redundant colons and very frequently dilated boggy cecums hanging low in the pelvis; but the spasticity and overirritability of other parts of the tract have seemed responsible for the loss of tone and of the decompensation apparent in these saccular loops and pouches. Atonia is relatively infrequent in the shorter bowel forms. It becomes apparent in the decompensated bowel segments of marked redundancies and in megacolon, and in these less evidence of hyperirritability appears, less of the functional make up of the hypervagotonic. In addition, there is an overacting sympathetic system which tends to continue the "status quo" in apparently dilated and decompensated large loops of bowel. The problem in these relatively few cases is to relieve the bowel stretching and decompensation and by various means block out the influence of the sympathetic system.

AUTONOMIC CONTROL

The main factors involved are the relative activity at various periods of the parasympathetic and sympathetic divisions of the autonomic nervous system. The parasympathetic (craniosacral), notably the vagus, is the activator, carrying fibers that increase secretion, produce spasticity and motor activity, and, if overstimulated, cause the excessive formation of mucus and lead to colic and hyperirritability. The sympathetic system (with its paravertebral ganglions) is the inhibitor or depressor, the direct antagonist of the parasympathetic. Stimulation or activity of this system leads to relaxation and loss of tone and to checking of secretion. Royle denies that relaxation is an essential factor of its activity but believes that excessive action of the sympathetic nervous system fixes any posture that is imposed, producing a fixation of plastic tone. He proved this idea by the operations of lumbar sympathetic ganglionectomy and ramisectomy in megacolon and decompensated redundant colons to relieve constipation when the bowel loops were fixed in form. Practically, pure cases of overactivity are never found of one system. The work of Bockus and his associates² shows that a general imbalance exists in the autonomic nervous system with varying degrees of overactivity.

2. Bockus, H. L.; Bank, J., and Wilkinson, S. A.: Neurogenic Mucous Colitis. *Am. J. M. Sc.* 176:813 (Dec.) 1928

of both systems, with that of the parasympathetic (vagus) more pronounced.

THE SPASTIC, IRRITABLE COLON AND MUCOUS COLITIS

As somewhat of a contrast, the hypertonic colopathies, which include the spastic colon, the irritable colon and mucous colitis as different phases of the same functional disorder, present not only the local bowel derangement but clearly a more apparent nervous and psychic disturbance. A preponderance of evidence indicates that the syndrome of the spastic, irritable colon is a visceral neurosis (in some respects akin to asthma) and exists only in persons with unstable or poorly coordinated nervous systems.

Fig. 1.—Variations in form of colon; essential tendency to redundancy and atonia. A, normal colon; B, redundant colon; C, atonic loop, redundant colon; D, megacolon; E, low descent of cecum; F, low descent of cecum after evacuation; G, irritable colon relaxed by enema; H, after evacuation.

As a group, intelligent and analytical, and excessively hypersensitive, they seem to have adopted a phobia of some disease (generally cancer) and an obsession, constipation.

It matters not that at the time advice is sought there may be many liquid and mucous stools a day, with great pain; this is usually considered but an episode. The thing that matters is the constipation that always comes, and the patient's fear of its results. As Dr. Lewellys F. Barker³ has so aptly summarized it, that "form of habitual constipation in which there is persistent spasm of the colon (hyperkinetic-dyskinetic constipation), often associated with paroxysms in which larger or

smaller quantities of mucus are passed from the bowel . . . is most obstinate and more and more difficult satisfactorily to treat, especially when it occurs in patients of outspoken hypervagotonic constitution."

Normal colon function includes fluid and salt absorption, a favorable bacterial digestive activity, and certain regulatory motor phenomena. These consist of the pendulum movements that mix its contents, peristaltic waves that send these onward to the distal bowel, and important antiperistaltic contractions that result in the retention of the contents in the cecum and ascending colon. Nature thus provides for a retention or favorable stagnation in the cecum, which makes possible bacterial digestion, absorption of fluids and soluble products, and the proper concentration of the excreta, insuring a formed paste in the distal bowel.

When the fluid contents of the cecum are projected rapidly to the distal colon, all the ills of intestinal indigestion result: irritation, fermentation, impaired absorption of intestinal gases, colonic spasm and pain, and systemic toxic effects. On the other hand, when the contents of the proximal colon are too long held up by dysfunction of the peristaltic and other motor activities, the dry inspissated residue produces a similar result, though with different characteristics. In either of these states a heightened irritability of the neural and muscular mechanisms of the colon exists, leading to spasms, an incoordination of the colonic contractions and often to hyperactivity and perverted secretion of mucous glands.

In functional colon disturbance are found (a) spasm most pronounced in the descending and sigmoid colon, (b) peristalsis and antiperistalsis greatly increased in the cecum and adjacent bowel with prolonged stasis and (c) excessive mucous secretion. An underlying neurosis is the essential factor that produces this type of habitual constipation and irritable colon. However, not all neurotic persons have irritable colons, and it would be a grave error to consider the neuroasthenia as the only provocative incentive of the disturbance. Of immediate importance may be states of debilitation and exhaustion from many causes, such as various infections, a thyrotoxic episode, inroads of child bearing, abuse of the intestinal tract with laxatives and enemas, and certain intoxicants, such as poisoning from lead and from tobacco. Undoubtedly, all these con-

ditions, plus emotional crises and the wear and tear of life, may bring in extraneous influences enough to set off functional disturbances that are held in abeyance. Intestinal neuroses diminish as one descends the social scale.

As a class, individuals with functional colon disorders are more or less unstable with an apparent imbalance of autonomic control of many involuntary functions, being easily excited, worrying, anxious, below par physically and frequently hyperanalytic and introspective. The intestinal complaint may be but a local manifestation of a general spasmophilic tendency. Outspoken vagotonia is frequently apparent. Migraine is common and asthma in the family history is not infrequent, as also are other allergic reactions. Sparseness, undernutrition, visceroptosis, active mentality, and

3. Barker, L. F. On the Management of the Spastic Colon and Mucous Colopathy, Especially in Hypervagotonic Persons, *Am. J. M. Sc.* 178: 606 (Nov.) 1929.

a too frequent impulse to "go on their nerve" are outstanding characteristics.

Wide pupils, erythemas, sweatings, irritable heart, variable blood pressure, fatigability and affective states abound. In many patients the evident and distinctive features of nervous instability and hypertonia are not casually apparent. Just as in migraine, the individual may seem most phlegmatic, reasonable and composed, and it is only when under strain, physically or mentally, or both, that the nervous instability can be recognized.

About 75 per cent of these disorders occur in women. While the age average is about 35 to 40 years, the condition may occur in the second to the fifth decade. Constipation and abdominal discomfort, often amounting to the severest pain, simulating disease in other neighborhood organs, are the leading complaints.

An abdominal unrest is evident, with sensations of rumbling, gurgling and bowel tremor, terrifying to the patient and greatly accentuated when, in the more irritable types, quantities of mucus are passed. The discomfort may be described as a tight feeling, or pressure sense, like a ball or lump or stoppage. This feeling may be diffuse but is more generally located in the lower part of the abdomen, especially on the left, with tenderness and soreness about the cecum.

While a gnawing sensation is frequent, the pain is usually a dull continuous ache, which may be general or localized. At intervals it may be spasmodic, but it is not rhythmic and not of the relentless immobilizing character of an acute inflammatory condition. To some it is agonizingly severe, localized accurately over the particular part of the colon in spasm, and even requiring relief by opiates. Ryle⁴ speaks of it as suggestive of major colic, localized or diffuse, lasting from hours to days, of variable frequency and occurring generally two or three hours after food has been taken. During the day it seems to incapacitate and depress the victim out of all proportion to the actual physical manifestations, but rarely disturbs sleep. Heat and rest give relief, as also will a bowel movement, generally.

The constipation may be mild but usually is obstinate and at periods may be excessive. With an increase of nervous irritability, periods of diarrhea ensue, and it is not unusual to have a regular interchange of small, dry, constipated stools for several days, followed by a shorter period of violent diarrhea with watery stools and mucus in great sheets and strings. The steady dull pain appears in the period of constipation, with severe paroxysms in the diarrheic, especially in conjunction with excessive quantities of mucus. The stools are difficult to pass and are always unsatisfactory to the patient, but they are negative for pus and parasites and usually for blood.

There is an almost invariable use of cathartics and enemas, partly because of a great fear that an organic obstruction or block exists somewhere in the intestinal tract, or of an unreasonable anxiety in reference to the constipation and systemic poisoning. There are chronic fatigue, chronic indigestion and a coated tongue.

Subjective flatulence and gas, with nervous eructations, may be present but does not cause objective

distention, except in the less frequent cases with fermentative intestinal floras.

On examining the abdomen, the keen observer will detect the excessive degree of complaint and the hysteria-like attitude as being unwarranted in comparison with the objective manifestations and realize that he is dealing with a barometric belly. Such an abdomen is markedly hypersensitive and flinches almost as it is touched; the lightest pressure on the skin is almost as distressing as deeper palpation. The ropy or cordlike sigmoid may or may not be felt. More characteristic, but present in only a moderate percentage of cases, is the abnormal cecum, either firm, prominent and resistant or lax, boggy and baglike, distended with material, gas and fluid, sensitive and tender, lying low in the inguinal region.

Elmer Eggleston⁵ estimates that from 20 to 25 per cent of these patients have had their appendixes removed (so-called chronic appendix) and in 5 per cent the gallbladders have been taken out without any improvement. The wise surgeon now knows that it is best to stay out of the "functional abdomen."

Fig. 2.—Differences in contractility of colon; essential tendency to short or normal lengths and hypertonia. A, redundant colon dilated and relaxed by enema; B, general spasticity; C, irritation type of segmentation, segmental spasm; D, irritable colon, feather sign; E, spastic sigmoid, dilated cecum; F, spastic colon, string sign.

DIAGNOSIS

The diagnosis is made primarily when a history and physical examination with the essential characteristics are secured. It is further sustained by a study of the stools, rectal and sigmoidoscopic examination and roentgen visualization of the gastro-intestinal tract.

The stools show great variation in form and shape, ranging from normally formed to mushy or watery, or with alternating periods of small, dry, marble-like masses, followed by diarrheic looseness and great quantities of mucus. They are essentially negative on microscopic examination, although occasionally a few blood cells can be noted.

The sigmoidoscopic examination is primarily important in ruling out early ulcerative colitis, amebic dysentery, rectal ulcer and neoplasm of the rectum and lower sigmoid. This examination should always be made.

4. Ryle, J. A.: The Study of Symptoms, *Lancet* 1:737 (April) 1931; Chronic Spasmodic Affections of the Colon and the Diseases Which They Simulate, *ibid.* 2:1115 (Dec. 1) 1928.

5. Eggleston, E. L.: Colitis—The Spastic Type, *J. A. M. A.* 91:2049 (Dec. 29) 1928; Common Disorders of the Colon Observed in the Treatment of the Chronic Invalid, *New Orleans M. & S. J.* 81:686 (April) 1929.

Spasm, irritability, moist normal looking mucous membranes, with perhaps a little injection and a rectum usually empty but containing mucus in varying amounts and appearance, are characteristic. The membrane everywhere is intact and normal appearing to the eye.

Visualization by the roentgen ray of different portions of the gastro-intestinal tract in functional disturbances of the colon, like the sigmoidoscopic examinations, is chiefly of value in demonstrating or ruling out pathologic conditions not related to form or function.

If none such is found, then the bowel form—namely, the length of the colon and degree of redundancy, amount of decompensation, and loss of tone in loops, presence of diverticula and position of the flexures—is next in importance. Finally, the degree of irritability present at that time may be demonstrated. This may vary at different periods from the normal form and tone previously shown to varying degrees of general spasticity, segmental irritation phenomena, hurried or delayed emptying, a spastic sigmoid with a large dilated cecum, a feathery descending colon simulating the appearance of the small bowel, and occasionally (10 per cent) the string sign.

The most important procedure is to follow the barium meal down through the tract to judge approximately the disturbance of motility and the degree of irritability, stasis and fermentative processes. The normal bowel is usually only partially empty, while in the irritable bowel only a trace of barium is left in the colon. The barium enema is important, but since it relaxes spasm it may mislead the observer entirely as to the motor function of the bowel.

PROGNOSIS AND TREATMENT

Patience and education finally bring these sufferers to relative stability and ultimately to almost normal health. The road is long and the way beset with relapses that develop with the ills that befall mankind and with unfavorable environmental conditions. The conquering of fear and other emotions, and the acquisition by them of a convincing insight into the nature of their sickness—psychologic control, in other words—is the great foundation for cure. The physician must develop this understanding and teach proper management for the overtonic colon, just as he must restore tone and compensation to the dilated and stretched loops and segments of the redundant and other atonic forms.

Aside from these considerations, more specific treatment of the condition is included in the following suggestions:

A. In the abnormal bowel forms with redundancy and atonic decompensated loops, immediate relief of fecal retention is indicated. Treatment should include small flushings or repeated colon siphonage, followed by oil retention enemas and oil by mouth; the use of a peristaltic excitant, such as ampoules of pitressin, and of thyroid extract (especially when the basal metabolism is lowered), and, finally, the avoidance of all belladonna preparations to aid and not deter the craniosacral system.

The diet should be bland but contain much soft pulp and vitamins, especially vitamin B.

Only in the more resistant and extreme cases of obstinate, persistent constipation should sympathetic ganglionectomy and ramisectomy be resorted to. Many cases of megacolon may require such surgical aid. In all other respects the treatment is essentially that noted under B.

B. In the hypertonic and more irritable states, I have found the following procedures of the most value in the management of the colon:

1. Overcoming physical exhaustion. Bed rest and convalescent care.

2. Psychologic directions and readjustment; securing a favorable environment and outlook.

3. Sedative aids adjusted to needs of the individual; mild hypnotics; antispasmodics, such as belladonna, uovotropine, phenobarbital, bromides and amylal. Empirical use of calcium salt in large amounts, with perhaps parathyroid or viosterol. Usually avoidance of thyroid and pituitary extracts.

4. Control of stools: First, there must be the elimination of all laxatives and irrigations. Then lubrication is instituted by mouth and rectal oil retention as needed, and nonirritating mechanical stimulants are started in the spastic stage, such as soaked soft agar or strained psyllium. Variation of the diet, according to the appearance of the stools, must be taught.

5. A bland and nonirritating diet. No roughage is allowed. Bran and other nonsoluble irritants are forbidden. The diet should contain a list of foods to be taken if diarrhea develops. As the stools become formed and then hard and dry, addition of puréed vegetables and fruits is indicated. Selected vitamins that do not induce laxative reaction should be given. There must be the accepted balance in protein, carbohydrate and fat intake, with emphasis on proper nutrition. Ultimately, it should be made as general as the tolerance of the bowel will permit. Some allergic adjustments may need to be made.

6. Symptomatically such aids as are necessary in controlling dyspepsia must be given consideration, such as colloidal kaolin for bowel fermentation and gas, or acidophilus cultures; use of dilute hydrochloric acid or alkalis; digestive ferments, especially pancreatin, and possibly yeast.

SUMMARY

A critical analysis of chronic disorders of the bowel leads to a recognition of inflammatory states with lesions of the mucous membrane, properly called colitis, on the one hand, and, on the other, of disturbances related to the form and function of the bowel.

These disturbances, characterized by constipation and irregular diarrhea, seem fundamentally to depend on bowel form, motor function and the constitutional make up of the individual.

The limited benefit resulting from correction of local abdominal and rectal lesions, intestinal flora and allergic intolerances must be admitted. In studying these conditions the bowel form (length, loopings, decompensation) as well as degrees of hypertonia and atonia must be considered. Knowledge of the rôle of the autonomic nervous system, as exemplified by the varying control of the craniosacral and sympathetic divisions, is essential.

There are features of the clinical history and examination characteristic of functional colon disorders; and the diagnosis is made certain by the relatively negative examinations of stool analysis, roentgen studies and sigmoidoscopic examination.

Treatment is essentially soothing and sedative; reconstructive both psychologically and physically. It must include a regimen of colon management, which has been outlined in detail.

ABSTRACT OF DISCUSSION

DR. LEWELLYS F. BARKER, Baltimore: Dr. Kruse has emphasized the importance for therapy of rather sharply separating the disturbances of function of the large bowel that are associated with abnormal colonic forms, such as redundancy and megacolon, from those that in the absence of such abnormal forms depend mainly on unbalanced autonomic innervation, as in the irritable colon, the hypertonic or spastic colon, and the so-called mucous colopathy. In the latter group of cases, a thorough general diagnostic study is important. One should not be content with a diagnosis of the disturbance of the functions of the intestine alone but should push the study far enough to reveal all important deviations from normal structure and function in the whole organism, making a corresponding multi-dimensional diagnosis before planning the therapy. A study of this sort inspires the patient with confidence that his physician has made sure of the conditions that actually exist and that therefore nothing important is likely to be overlooked in treatment. Disturbances of the general state of nutrition, often with marked emaciation, are frequent accompaniments, as are functional neuroses and affective disorders of cyclothymic tendency. Adequate treatment of these when found may be the best measure also for overcoming the colonic disturbances. That organic disease of any of the abdominal or pelvic organs should be discovered if present and duly evaluated goes without saying. Surgery will sometimes be indicated, of course, but far less often than many general practitioners have thought. Unnecessary surgery does more harm than good, prolongs the illness, and, by its failure to cure, increases the discouragement of the patient. Dr. Kruse has outlined the fruitful medical measures, including general upbuilding, a caloric intake of bland diet suited to the caloric and metabolic needs, adequate physical and mental rest, sedatives for the nervous system, antispasmodics, especially methatropine, for the hyperkinetic colon, and careful kidney guidance with repeated reassurance during supervision until health is restored.

DR. WALTER L. PALMER, Chicago: The first problem in dealing with what I choose to call "bowel distress" is that of the exclusion of organic disease of the bowel. The term "colitis" should be reserved, as Bagen and others insist, for organic inflammatory disease of the colon. The diagnosis of amebic dysentery, nonspecific ulcerative colitis or carcinoma is ordinarily not difficult if one follows the usual procedure of a careful history, complete physical examination, endoscopic examination of the rectum and lower sigmoid, careful search in the stool for pus, blood and parasites, and finally roentgen examination. The second problem is that of excluding organic disease elsewhere in the body. I have in mind particularly early pulmonary tuberculosis and thyrotoxicosis, diseases that frequently manifest themselves by means of abdominal distress and for which the physician must always be on the watch. Cholelithiasis, peptic ulcer, carcinoma and other intra-abdominal diseases frequently simulate "bowel distress" and are easily overlooked. After organic disease has been excluded, there still remain, as the author has pointed out, the so-called functional cases of abdominal distress with chronic diarrhea or constipation. Much has been written of redundances and loopings, of mobile and immobile cecums, of high lying cecums and low lying cecums, of autonomic imbalance, of visceroptosis, and so on. It is necessary to maintain a critical and somewhat skeptical attitude toward all these innovations. The important consideration is not where the colon lies or how it twists but rather how it functions. This problem is relatively simple, for colonic function depends on the treatment the colon receives. Continued catharsis, repeated enemas and injudicious dietary habits result in colonic irritability, which usually subsides promptly when a bland diet is instituted and the chemical and mechanical insults to the colon are discontinued. In many cases, however, the disturbance cannot be related to dietetic or cathartic habits, and a diagnosis of visceral neurosis is made. This is the group of patients to which the author's phrase "the barometric abdomen" is particularly applicable. The abdomen is the barometer of the individual and attention should be directed not toward the bowel alone but rather toward the total personality of the patient. Every one is familiar with nervous diarrhea as an acute episode associated with some emotional disturbance, but

many fail to appreciate the frequency with which chronic motility derangements of the intestine are merely the organic manifestations or reflections of chronic emotional stress. In general, the colonic patient taxes to an unusual degree both the diagnostic acumen and the therapeutic skill of the physician.

DR. E. L. EGGLESTON, Battle Creek, Mich.: Dr. Kruse has called attention to a particularly severe type in which the diagnosis is easily made. On the contrary, a patient with mild involvement may suffer from symptoms only when under emotional stress, but if the cause is not relieved the trouble becomes more persistent and finally chronic. While constipation is the rule, an occasional loose movement may occur, after which the patient may complain of greater discomfort. The trouble is not primarily intestinal in origin. A nervous instability resulting from emotional stress, an anxiety state, is primarily the cause of the colon dysfunction. The autonomic nervous mechanism is not affected by the will but is profoundly disturbed by the emotions. This disturbance may not be limited to the colon but may affect the entire gastro-intestinal tract. Most of these cases when observed under the x-rays exhibit a rapid emptying stomach and small intestine, and the barium may reach the pelvic colon in two or three hours. Here the intestinal contents encounter an obstruction due to a more or less tonic spasm of the pelvic colon, so that what appears to be a rapid emptying of the colon develops into a very obstinate constipation. It is unfortunate that the causes of the instability of the autonomic nervous mechanism are not more thoroughly understood. Emotional strain, anxiety and insomnia are potent factors in causing this disturbance. That it is not due to dietetic indiscretions or to infections is apparently proved by the Negro. While his dietetic habits are notoriously bad and his use of liquor and tobacco is excessive, he is definitely susceptible to different types of infection. He apparently has not yet acquired the ability to worry and so is spared these troubles which are so distressing to his white brother. Not only is he free from the spastic colon, but peptic ulcer is rare among his race. I fear that Dr. Kruse may have left the impression that the hypertonic colon obtains in the physically unfit only. This, I regret to say, is not the case. Its presence is rather a mark of an advanced civilization, of a highly organized nervous mechanism. I am of the opinion that a sympathicotonia obtains more commonly with those individuals who are physically unfit from birth. There are those who consider the hypertonic colon an allergic reaction because of its similarity to asthma. Until more is known about the causes of allergy, I think it best to consider it a vagotonic manifestation, and I am in accord with Dr. Kruse in emphasizing that the real cure comes as a result of education rather than from some method that may temporarily relieve the constipation.

DR. WILLIAM LINTZ, Brooklyn: I find that most colopathies are in reality of allergic origin. The symptoms differ in no wise from those described. Of all the manifestations of allergy I find that the intestinal form is by far the most frequent. Bacteria and their toxins, foods and their split products, the most frequent of all, allergens, are found there in greatest amount. Histamine, with which one can reproduce all the various manifestations of anaphylaxis, is normally found there. The history is the most important point in the diagnosis and treatment of these patients. There are present other allergic manifestations in the patient, relatives and offspring. The skin testing in allergy depends on this principle. Allergic skin manifestation is so frequent in this intestinal form that it should be considered a symptom of the syndrome. The family history of allergy in relatives and offspring I found in 61 per cent of my series. Allergic intestines differ from all others in that a certain article of diet will give rise to moderate or violent symptoms. "Eggs gave me severe cramps and diarrhea." Milk or oatmeal act as physics. The odor of cooking chicken, lamb and fish produced bronchial asthma, and soups from these foods produced abdominal pain, cramps and diarrhea without asthma in the same patient. The bacterial flora and their products may act as a sensitizing focus on the allergic bowel. In one patient not only the colitis but the asthma as well vanished after the eradication of infected foci. The allergens producing intestinal manifestations are legion. A patient had constipation for days every time he took oatmeal. It took four different trials to convince another patient that liquid

petrolatum was the cause of his constipation. Surely, what is one man's meat is another one's poison. Quite frequently these patients turn tables to their advantage when they discover foods that have a mild hypersensitive effect on their allergic bowel, as when they use milk and numerous other foods as a laxative. A strong point in the history is that the elimination of the offending food eliminates the bowel symptoms and its restoration provokes it. When the vagus dominates, the patient is much more sensitive to his allergens. Allergic individuals are influenced psychically through this route. Not only the abdominal symptoms but the other neurologic and allergic manifestations disappear with it. Skin tests are correct in only 50 per cent of cases. This allergic bowel should be the last diagnosis. Every other lesion should be excluded first. The treatment should be the determination and exclusion of allergens or desensitization when this is impossible.

DR. FRED H. KRUSE, San Francisco: There are two issues that I will consider further: One is the matter of surgical treatment, its necessity and what one may hope to gain from it. Dr. Barker has emphasized the importance of a careful diagnostic survey as a preliminary measure in the care of patients suffering from functional colon disorders. Suppose in such a case stones are found in the gallbladder or a fibroid tumor in the pelvis. What is to be done about it? I have seen patients with irritable colon and quiescent pathologic conditions of this sort operated on without any resultant reflex benefit or improvement. In the long run, the patients have only a disturbing episode with an exacerbation of the chronic colon disorder to remember, and a continuance of the original disturbance. I believe that the course one is going to take should be determined by the nature of the physiologic disturbance present. When there are indications of apparent gallbladder dyspepsia, or evidence of trouble from a fibroid uterus, these should be removed. But they should not be removed with the idea that the patient will get a great deal of help for the irritated colon, especially if in the history and examination it is found that the patient has the earmarks of the constitutional and psychic make-up described here. I have been disappointed when such operations have been carried out. Ten years ago I did that regularly. If one operates on such patients for something that isn't really causing the bowel disorder, they are apt to spend three or four or six months in bed and are made much worse. Secondly, in reference to allergy, I agree with Dr. Lintz that there are many people who have allergic bowel reactions, exacerbating at least a chronic colon disorder. Such conclusions have been forced on me in several cases. All these possibilities must be kept in mind. Food allergy must be thought of. But, by and large, if the syndrome I have described is evident, both in the physical make-up and in the nervous and physiologic responses of an individual, sad experience has taught the futility of relying too heavily on the aid of surgery or allergy, be it by the desensitization or the food elimination method. I have tried them all.

Inspiration and Medical Schools.—The last function of a medical school or faculty that need be mentioned here is that of inspiration. It must be a poor school or university which cannot supply this, either through its general atmosphere or through the personality of one or more of its teachers. It is a real thing, and a necessary thing for the medical practitioner. Without it the student's acquirements will be imperfect, and his work, both during his studentship and thereafter through his professional career, a burden, or at least a source of infinitely less satisfaction than it might otherwise have been. In the words of Littré, "La puissance de l'éducation consiste à augmenter le nombre des motifs dans l'esprit de l'individu." If the student is not put in the way of acquiring, or of developing, some width of culture, a zest for knowledge, a love for his work, a real sympathy with human suffering and trouble, a profound respect for confidence reposed in him, an appreciation of nobility of character and of the dignity and peculiar requirements of professional life, to that extent will the contribution made by the medical school to his medical education have failed of its complete purpose, and to that extent will he pass out from it a liability rather than an asset to his profession and to the community.—Brackenbury, Sir Henry: The Training of the Medical Practitioner, *Brit M. J.* 2:381 (Sept. 1) 1934.

Clinical Notes, Suggestions and New Instruments

WHOOPIING COUGH CURED BY MUMPS

REPORT OF TWO CASES

EDMUND W. KLINEFELTER, M.D., YORK, PA.

Feb. 28, 1934, a mother of three children called me on the telephone, stating that her three children had whooping cough and were vomiting after each coughing paroxysm. I went to see the children on the same day and confirmed the diagnosis made by the mother. Each of the three children, a boy of 14 months, a girl of 3 years and a boy of 5 years, showed typical attacks of coughing followed by vomiting when I made an effort to examine their throats.

The oldest boy had been showing the typical paroxysms for the past week, the other two for only the past two days. For the past two days the paroxysms were occurring from three to four times every hour. The mother told me that either one or the other of the children would start off on a coughing spell and then the other two would join in. There was no elevation of temperature. Under antipyrine, belladonna and amylal medication a prompt diminution occurred in the number and severity of the paroxysms in the younger children. The 5 year old, however, was made worse by the antipyrine, belladonna and amylal. Therefore, March 3, I stopped giving this medication to the 5 year old and began the rectal administration of ether in oil. The ether in oil produced no improvement and was discontinued on March 6.

March 6, the mother called me early in the morning stating that the 5 year old had a swelling on the right side of his face about the size of a grapefruit. Examination showed the boy to have a typical case of mumps with the high temperature of 104 F. by mouth. Inspection of the throat at this time did not elicit a coughing paroxysm. From March 6 on there were no more paroxysms. Nourishment was taken without coughing or vomiting. At times there was a slight cough but no typical whooping cough. By March 12 the child was perfectly well with a normal temperature and no evidences of whooping cough or mumps. From March 6, no medication was administered. Pink and white colored blank tablets were given as placebos.

March 9 the 3 year old child developed a swelling on the right side of her face. Examination showed that this child also had a typical case of mumps. The temperature by rectum was 101 F. Inspection of the throat at this time did not elicit a paroxysm. With the onset of the mumps there was likewise in this case an abrupt cessation of the coughing paroxysms. By March 10 the temperature was normal and the antipyrine, belladonna and amylal medication was stopped. By March 17 the mumps had completely disappeared and the child was perfectly well. Neither during nor after the attack of mumps were there any whooping cough paroxysms.

Up until the middle of May, the 14 months old child suffered from typical whooping cough paroxysms. From May 15 on there was gradual improvement. The intermittent administration of antipyrine, belladonna and amylal served nicely to control the cough in this child.

Numerous cases are reported in medical literature showing that at times one disease may exert a favorable or curative influence on another disease. It has been reported that whooping cough can be checked during the eruptive stage of chickenpox. However, after the disappearance of the eruption the paroxysms again become severe.¹ Apparently vaccinia at times exerts a favorable influence on whooping cough.² Tuscherer³ observed two cases of whooping cough that were suddenly checked by an attack of measles. A review of the literature has shown no report of a case of whooping cough benefited or cured by an attack of mumps.

Special Article

THE TREATMENT OF CHRONIC BRIGHT'S DISEASE

CLINICAL LECTURE AT CLEVELAND SESSION

JAMES P. O'HARE, M.D.

BOSTON

The term "chronic Bright's disease" includes essentially three diseases: chronic glomerulonephritis, chronic vascular nephritis and chronic nephrosis. For this discussion on treatment, it is permissible to consider chronic glomerulonephritis and chronic vascular nephritis as one disease—chronic nephritis with hypertension.

There is nothing new or startling in the treatment of this nephritis. The therapy of the condition is more or less standardized in all textbooks, and until the late stages it is quite effective. In the uremic stage, treatment is at best palliative and eventually, of course, ineffectual. For such a gathering as this no detailed discussion of the standard treatment is, of course, necessary. It should suffice merely to indicate general principles and then to stress certain features that seem to me to be especially important and worthy of your attention.

The commonly accepted treatment aims at three primary objects:

1. First and foremost is the maintenance of the health of the whole body.

2. Secondly, it seeks the elimination of all toxins that in passage through the kidneys may increase the progress of the renal lesion. This means the eradication of all true sources of infection. It does not, however, mean ruthless surgery on such structures as the teeth, tonsils and sinuses that are mere objects of suspicion. It means also the avoidance of intercurrent infections as far as possible and prompt and efficient care of them when they do occur. It means proper care of the bowels to eliminate poisons from that source. Finally, it means a diet constructed to avoid undue strain on the kidneys by all products of excretion.

3. Lastly, signs must be recognized and cared for and the patient given relief for his symptoms as they arise.

The most important form of treatment, without doubt, is a diet that aims at a proper balance between food intake, the ability of the kidneys to excrete end products, and the general needs of the body.

Because of the enormous reserve power of the kidney, no great dietetic restriction is necessary or desirable in the early stages of this disease. Nothing more than simple instructions to avoid any excessive intake of protein, salt and fluid seems indicated. Meat or fish once a day, no salt added to the food after it comes to the table, and fluids limited to 4 pints is sufficiently restrictive.

As the disease advances and renal function falls, one is forced to make greater and greater restrictions. Much harm, however, can come from excessive protein reduction. Occasionally conditions demand a modified Karrell diet or a very low protein ration. These diets should be prescribed only with a full under-

standing of one's aims and the dangers involved. They should be used for as short a time as possible, after which there should be a prompt return to a basic dietetic regimen. For the last a good general rule to follow is this: As far as one possibly can, one should try at all times to give the patient a mixed diet of sufficient calories, with about 1 Gm of protein per kilogram of body weight. The salt intake should be limited to that which is in the food when it comes to the table (from 3 to 5 Gm). The fluid intake, at first restricted to 4 pints or less, may be increased gradually and carefully, as renal insufficiency becomes greater, up to 6 pints a day. This increase is to take advantage of the polyuria, which allows an excretion in dilute concentration of substances that cannot be eliminated in more concentrated form.

When renal decompensation has become great and definite signs of uremia appear, therapy is often difficult and unsatisfactory. It is necessary at times to choose between several evils. If one institutes too rigorous protein restriction to decrease the kidney load, the patient's own tissues may break down and increase the toxemia. If excessive fluid is administered, the heart may be embarrassed. If the patient is vomiting, much chloride may be lost and produce symptoms. Incidentally the blood chloride is often low in the late stages even without vomiting. Increased intake of salt by mouth or by clyses may be required.

In the vomiting patient the problem may be particularly difficult. Experience has taught me that the best solution for this problem is for the doctor to confine his attention to the administration of an adequate amount of fluid in the form of salt solution and dextrose given by vein, under the skin or by rectum. The feeding of the patient should be turned over to some tactful nurse or dietitian, who will often succeed when the doctor cannot. No restriction whatever should be placed on what she may feed the patient, although the protein-sparing carbohydrates should be encouraged. Every effort should be made to satisfy the patient's demands, no matter how queer they may seem. It is a well known fact that a patient will retain something he craves and reject foods that have no appeal. If he asks for beer and a ham sandwich, give them to him; he may retain them. Once the vomiting has ceased, the patient should be put back on his former diet.

The rest of the treatment of chronic hypertensive nephritis is purely symptomatic. No therapy for the anemia is entirely satisfactory. Iron in the form of pills of ferrous carbonate (Blaud's pills) has been used from early days without, however, much success. This lack of success may well be due to interference with absorption of this substance. Perhaps if the drug were given in 10 grain (0.65 Gm.) doses before meals greater success would be obtained. Transfusions, though of some value late in the disease, have merely a transitory effect.

Many of the cerebral symptoms that occur in uremia are said to be due to the absorption from the large bowel of toxic phenols and cresols, which seem to get into the circulation with great ease in these late stages. Cleansing the bowel by frequent saline catharsis and enemas seems to constitute the only remedies. These, by exhaustion of the patient, may introduce other difficulties. Sedatives, of course, are necessary. Of these phenobarbital by mouth or by injection, and chloral by rectum, are the most generally useful. For the con-

vulsive seizures, threatened or actual, magnesium sulphate (intramuscularly or intravenously), morphine sulphate, intravenous dextrose and possibly lumbar puncture are to be considered. For the extremely uncomfortable itch, nothing is as effective as sponging with vinegar or weak acetic acid. It is to be borne in mind that all drugs excreted by way of the kidney are retained longer when renal insufficiency is marked. Their effect is therefore more prolonged and more pronounced.

I will now consider certain parts of the problem that, to my way of thinking, require special attention. Ever since Bright's name was first given to this disease, many doctors have regarded nephritis as a disease of the kidneys alone. Intelligent treatment demands above all else a recognition of the fact that this is decidedly not so. In fact, there is no form of nephritis, acute or chronic, in which the disease is confined to the kidneys. Intelligent treatment demands further the realization that in many a patient the disturbances of other organs are far more serious and require far more attention than do the kidneys. The thoughtless physician who focuses his "oil immersion" on the kidneys alone may be rudely jolted by the sudden death of his patient from a heart attack or a cerebral hemorrhage. In his lack of knowledge he may attribute these to uremia. This is not merely incorrect but bad medicine. By recognition of what is going on and by the institution of appropriate therapy it is often possible to avoid such accidents. In the Peter Bent Brigham Hospital more than half our patients with chronic Bright's disease die from a nonrenal cause, often long before the kidneys have become completely insufficient. It is well then in every case of this disease to bear in mind at all times the condition of the heart, the cerebral vessels and the height of the blood pressure.

Often a remedy that might be of value for the kidneys is distinctly harmful to the heart. I have seen several patients develop pulmonary edema from too enthusiastic administration of fluids or from sweat baths, which, fortunately, have now been largely discarded. Even excessive purgation may exhaust the patient and bring about cardiac decompensation.

Another point that needs stressing is the danger of overtreatment. Great harm can come from too great dietetic restriction. In the past, physicians were undoubtedly all guilty in this respect. Patients were kept on a very low protein ration for long periods on the theory that the work of the kidneys was being spared. The rest of the body was neglected. Sister Mary Victor of the Mayo Clinic has made it plain that any diet containing less than 40 Gm. of protein cannot supply an adequate mineral content. Diets of 40 to 50 Gm. contain insufficient phosphorus and iron. Only diets containing 60 Gm. of protein or over are entirely adequate. This, of course, does not mean that one should never prescribe low protein diets. Such a diet should, however, be used only for a short period and with full knowledge of the risks involved.

The treatment of chronic lipid nephrosis is not so thoroughly standardized or satisfactory as that of chronic hypertensive nephritis. The results of therapy are exasperatingly variable. At times a brilliant result is achieved. More often, however, the brilliancy of the therapy is only apparent and the results have little to do with the form of treatment used. Spontaneous diuresis is almost the rule. The utmost conservatism,

therefore, must be maintained in the interpretation of any therapy. Let me illustrate:

On one occasion during ward rounds I suggested the intravenous injection of hypertonic dextrose for a markedly edematous patient and on my next visit was greatly pleased to note a doubling of the previous daily output of urine. Imagine my embarrassment when, after expressing great delight at the success of my suggestion, I was informed by the stammering house officer that he had forgotten to give it.

I recall vividly another patient on whom every known form of therapy had been tried over a period of three to four months without success. Because of some apparent infection of the teeth, the hospital dentist was consulted, and he advised the extraction of two teeth. The consultation occurred on Monday. He returned on the following Thursday and extracted the teeth. A diuresis was instituted and the patient in the course of the next few weeks became entirely edema free. From the point of view of the dentist and the interpretation of therapeutic results it was most unfortunate that his consultation occurred on Monday and the extraction of teeth on Thursday, for the diuresis started on Tuesday, the day after he first saw the patient. I am sure any one would have been justified in claiming "cause and effect" if the teeth had been removed on the day the patient was first seen by the dentist.

Finally, all treatment may be absolutely ineffective. Even treatment that has previously been known to produce a diuresis in a given case may fail to obtain a result at a later date.

The "sheet anchor" in the treatment of lipid nephrosis is undoubtedly the replacement of lost blood proteins by the high protein diet originally devised by Epstein. It no longer seems necessary to use the low fat intake originally suggested by him. This serves no useful purpose and apparently makes for greater difficulty in feeding the patient. For some time it has been our program to give a mixed diet containing adequate calories and protein ration of 100 to 150 Gm. daily for a period of from two to three weeks. This is usually enough to give the body a chance to replenish, to some degree at least, the depleted blood proteins. At the end of such a period the high intake has usually begun to become monotonous or difficult for the average patient. It is then wise to drop back to about 1 Gm. per kilogram of body weight, plus the average amount of albumin lost daily through the kidneys. The diet should, of course, be salt poor and the fluid intake limited to 1,000 cc. or less. In some patients with very low output (from 300 to 500 cc.) Volhard has advised an intake each day equivalent to the urinary excretion of the previous day.

Unfortunately it is only on a rare occasion that this high protein ration alone is sufficient to produce a complete clearing of the edema, and recourse must be made to other forms of therapy. Epstein and others have felt that the administration of thyroid extract adds to the value of the high protein regimen. My experience with this drug has been very disappointing.

Next to the high protein diet, the most successful therapy in my hands has been the administration of the mercurial diuretic salyrgan, given in doses of from 1 to 2 cc., intravenously or intramuscularly, every three or four days. It seems to work best in the presence of an acidosis, produced by the oral administration of from 8 to 12 Gm. of ammonium chloride each day. Other diuretics and other drugs producing acidosis have not

been as effective. Salyrgan is open to the objection that it must be injected by needle and is distinctly irritating. It may produce thrombosis of the veins, and if any of the solution gets into the subcutaneous tissues a painful slough occurs. The intramuscular route is perhaps more commonly used, but the results are not quite as good as when the drug is given intravenously.

Salyrgan sometimes fails, and for one reason or another its use may not be possible. One must then turn to other methods, most of which are, by and large, less effective. Urea by mouth, in daily doses of from 20 to 100 Gm., is probably the next best drug. Calcium chloride in doses of from 8 to 12 Gm. a day, and potassium chloride, from 2 to 5 Gm. a day, are worthy of trial. Barker of Chicago makes successful use of the latter drug in his high potassium, low sodium diet, which consists essentially of a neutral ash diet with the addition of considerable potassium chloride by mouth. Perhaps the success of the "alkaline therapy" of Osman and Izod Bennett may also be due to the high intake of potassium salts in the solution recommended by them. This treatment, which on occasions I have found to be effective in cases in which nothing else seemed to work, consists in keeping the urine alkaline with a strong solution of potassium citrate, potassium bicarbonate, sodium citrate and sodium bicarbonate.

Lashmet has reported excellent results with his "acid-ash diet." This, too, is primarily a neutral ash diet plus hydrochloric acid. My experience with this has been limited and not entirely favorable.

Repeated transfusions are worth considering, the object being the quick replacement of protein and the increase of osmotic tension. The results in our clinic have not been particularly striking. I have not found it necessary to use the treatment devised by Hartman to increase the osmotic tension of the blood. He claims excellent results by the intravenous injection of 30 per cent acacia.

When accumulations of fluid in the body cavities become embarrassing they must be removed mechanically. Fluid can be drained out of the legs by means of incisions or the Southey tubes. These methods, however, are at times extremely dangerous because of the probability of local infection, particularly the dreaded erysipelas. The previously outlined forms of treatment are those most commonly used and are, I believe, most worthy of consideration.

Brilliant results are obtained frequently in the treatment of syphilitic lipoid nephrosis by careful anti-syphilitic treatment plus the high protein diet.

In the early stages of nephrosis complicating chronic glomerular nephritis when renal function is good, the previously suggested treatment can be carried out. As renal function fails, however, great care must be exercised. The high protein diet may produce a marked rise of the blood urea nitrogen to levels that are dangerous. The protein intake must then be cut to definitely lower levels. Fortunately at this stage, with a progression of the glomerulonephritis, edema tends naturally to disappear, and treatment for the latter is less necessary. Diuretic drugs in glomerulonephritis are not effective and may well be followed by an actual decrease in urinary output, with signs of renal irritation.

In conclusion let me stress the three following points:

1. Chronic hypertensive nephritis is not a disease of the kidneys alone. Intelligent treatment demands an intelligent understanding of all the problems involved.

2. Overtreatment may be quite as harmful as undertreatment.

3. Chronic nephrosis is fully as great a nonrenal problem as chronic nephritis. Before thoroughly satisfactory treatment for this condition can be devised, much new knowledge must be forthcoming.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

DISCUSSION OF PREVIOUSLY PUBLISHED ARTICLES

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

THERAPY OF FRESH ACCIDENTAL WOUNDS

To the Editor:—I have just read Dr. Bernard Fantus's article in *Therapeutics* in *THE JOURNAL*, July 14. Speaking of the treatment of fresh accidental wounds, he says: "If anesthesia is required for the treatment of the wound, nitrous oxide-oxygen inhalation is the agent of choice." No mention is made of the use of local anesthesia, and I suppose from my observation that it is either a general anesthesia or nothing in common practice. For many years I have been infiltrating the edges of such accidental wounds after a preliminary cleansing, to facilitate a proper painless cleansing, and placing of the necessary stitches. When the needle for infiltration is started through the fresh wound surface, it is painless. I have never seen any other physician use local anesthesia in such a case and after many trials can see no insurmountable objections to the method.

M.D.

DISCUSSION.—The suggestion advanced no doubt has distinct merit. The only question is whether wounds thus treated under local anesthesia might not be more susceptible to infection than those that are not. This question, of course, can be settled only by extensive clinical experience with adequate control. Such experience, no doubt, exists in the keeping of the dental profession. A query was sent to a number of eminent dental surgeons. Unfortunately, the replies were not such as to permit definite conclusions. There were practically as many opinions advanced that extraction wounds inflicted under general anesthesia healed more kindly than those under local anesthesia as there were that no difference existed. The entire situation is a good example of the need for controlled observations in therapeutics.

THERAPY OF CONJUNCTIVITIS

To the Editor:—I have been much interested in the article on the treatment of the eye by Dr. Gifford, as I have some positive ideas on the treatment of gonorrheal cases with silver nitrate.

In his treatment of ophthalmia neonatorum, I do not think he gives silver the credit it deserves. He puts much stress on irrigation, which certainly is of value; but the real cure of these cases is the silver nitrate when properly applied. He speaks of several drugs and says "They may be useful."

I believe it a crime for a baby to go blind with gonorrheal ophthalmia. I believe every case can be cured with perfect results as far as vision is concerned. In an experience of forty years I have never lost an eye in an adult or babe in my own cases. From 1893 to 1898 I had the eye clinic at the Cook County Hospital, where we had ophthalmia neonatorum in

abundance. And at the Post-Graduate Hospital for about thirty years gonorrheal cases were not scarce.

At the Cook County Hospital I learned the following method, which if faithfully followed will always give the best of results:

A swab is made on an applicator or a tooth pick (not too large) and dipped into a 25 per cent solution of silver nitrate and any surplus wiped off. The lids, which are usually much swollen, are then everted and gently painted with the silver. A nurse, ready with a dropper of water, washes off any surplus from the everted lids. This is not absolutely necessary, as I have treated cases alone and closed the lids at once and have never seen bad results following this. The lids must be treated twice a day, and at the end of a week the eyes will be on the way to a rapid recovery. It is surprising how rapidly the swelling will subside. Sometimes there will be a discharge after the eyes seem well; this conjunctivitis will disappear in a day or two with the following prescription:

Rx Antipyrine	3 grains
Hydrastis, solid extract.....	5 grains
Boric acid.....	10 grains
Distilled water.....	1 ounce

Sig. One drop in the eye several times a day. The solid extract must be used, as the fluid extract or the tincture does not work efficiently.

The possibility of injury to the cornea with such a strong solution is nil. I had an ulcer on a patient who had lost the right eye by the most foolish treatment by a family physician, and when he found the gonorrheal infection commencing in the left eye he turned the case over to me. The ulcer extended horizontally across the cornea from edge to edge and was about 2 mm. in width. Besides treating the lids I painted the ulcer with the 25 per cent silver. The eye was saved and the cornea remained clear with good vision. I have seen the patient many times in the past thirty years and she has retained useful vision, but in her old age she has had to contend with a glaucomatous attack. I have treated many gonorrheal ulcers in the same way, with satisfactory results. C. W. HAWLEY, M.D., Chicago.

DISCUSSION.—The letter was referred to Dr. Sanford R. Gifford, who writes: "I do believe that silver is indicated in some cases of gonorrheal ophthalmia but that most patients, especially children, get along as well, and perhaps better, without it if irrigations are efficiently performed. The 25 per cent silver nitrate solution is stronger than I have ever seen it used, and I doubt if it would be wise to advise such a solution for use by the average man. I have used 4 per cent and 8 per cent."

THERAPY OF FURUNCULOSIS

To the Editor:—Will you allow me to submit a treatment for furunculosis of the external auditory canal, which I have used over a period of fifteen years and which is not hastily devised or used without the most critical of observations. Failure is so rare that I resort to no other remedy. Pus formation occurs in a small percentage of cases, not to exceed 5 per cent, in the form of a small drop of pus, which comes away on the cotton; or, if the pus has approached the surface, it can be gently opened with an applicator.

As soon as a point can be localized or even when there is a general pain in the canal of the ear that one suspects may lead to furunculosis, pack the ear, over the tender point, with a cotton wad as solidly as it can be tolerated by the patient. The procedure is exactly this: Take as large a piece of cotton, of the very highest grade, that you think can be compressed into the canal of the ear. Then with any blunt instrument, such as the handle of an applicator, start to knead the cotton into the canal, and as the canal becomes filled and the plug of cotton becomes harder, it will be better to take some flat instrument like the one prong of a dressing forceps and fold the cotton in around the edge.

This treatment is quite painful, and the pain persists for from one-half to one hour, after which the pain ceases. The

patient returns in twenty-four hours. If the pain is relieved and the cotton is in place and firm, it is left for another twenty-four hours. If the cotton is not firm and in place or if the patient is in pain, remove and repack with cotton. Furunculosis thus treated generally does not come to the formation of pus. It practically always disappears without this. The case that comes to the formation of pus usually has but one drop.

HARRY A. SMITH, M.D., Whittier, Calif.

MYCOTIC INFECTION OF THE NAILS

To the Editor:—In an article by Dr. Bernard Fantus on the therapy of the mycoses (THE JOURNAL, September 15) it is stated that surgical removal of the nails is advised in stubborn cases of onychomycosis. Having studied and treated a goodly number of such cases the past five years, I do not believe that surgical treatment is either advisable or necessary. If the case is really fungous in origin, which must be proved either by microscopic or by cultural methods, conservative local therapy will produce a cure. Often clinical diagnosis of ringworm of the nails is really psoriasis. When the etiology is absolutely proved, competent treatment will cure, whereas the condition often recurs after surgical removal, which is drastic therapy.

CLEVELAND J. WHITE, M.D., Chicago.

TOXIC EFFECTS OF EMETINE HYDRO- CHLORIDE—FEVER REGIMEN: USE OF ALCOHOLIC BEVERAGES

To the Editor:—I have been reading with interest and profit "The Therapy of the Cook County Hospital," edited by Dr. Bernard Fantus. There are, however, two therapeutic points that I should like to mention.

In connection with the treatment of amebiasis (THE JOURNAL, June 9, p. 1940), I fully agree with Dr. Fantus that emetine hydrochloride is very efficacious for the control of dysenteric symptoms but I think that greater emphasis should be given to the toxic effects, which in my experience are frequent even when the average dosage is employed. For example, I have repeatedly been obliged to discontinue emetine therapy on account of the appearance of circulatory disorders even before the usual course of from 7 to 10 grains in daily doses of 1 grain had been completed. Marked reduction of blood pressure was observed repeatedly and it may persist for weeks if not for months.

I believe that (a) the use of emetine hydrochloride should be restricted to cases of severe, acute dysentery or of liver abscess of amebic origin; (b) the patient should be confined strictly to bed while this drug is being used, and (c) the blood pressure, pulse rate and cardiac rhythm should be observed and recorded at least twice daily when emetine is being used.

The following articles contain information on the toxic effects of emetine:

- Shattuck, G. C.: Outline of Treatment for Amebiasis, with Special Reference to the Use of Emetine, *Boston M. & S. J.* 190:766, 1924.
- Anderson, H. H., and Reed, A. C.: Untoward Effects of Antiamoebic Drugs, *Am. J. Trop. Med.* 14:269, 1934.

In the article entitled "Fever Regimen" (THE JOURNAL, August 18, p. 486) it is recommended that alcohol be administered freely to addicts when suffering from fever and that "in patients difficult to feed, most especially the aged, smaller doses . . . may be given with food."

I agree that addicts should not be deprived of their usual dose of alcohol during an attack of fever, but I believe also that alcohol may be used with even greater freedom in some cases of chronic infection with fever in which emaciation has resulted largely from inability to assimilate ordinary food in sufficient quantity. Under these conditions, even young persons who have never taken alcohol may absorb and utilize large quantities without showing the slightest evidence of intoxication and may, on the contrary, benefit greatly thereby.

GEORGE C. SHATTUCK, M.D., Boston.

PATENTED LENSES

FACTS VERSUS ADVERTISING COPY

ALFRED COWAN, M.D.

PHILADELPHIA

Theoretically, an ophthalmic lens should be free from the faults of chromatic aberration, curvature of field, distortion, annoying reflections from the surfaces and astigmatism of oblique pencils; but it is impossible to correct all these faults in a lens made of a single piece of glass.

Clinically, however, it is known that chromatic aberration, distortion and curvature, in ordinary ophthalmic lenses, are not noticeable enough to cause discomfort to the wearer. Reflections from the surfaces are sometimes annoying but can usually be remedied by proper adjustment. The spherical aberration that must be corrected in a photographic lens in order to produce a clear image to the edge of the plate does not apply to an ophthalmic lens. A clear image out to the periphery of the retina, even if it were possible, could not be appreciated. The retinal image is distinctly seen only over an extremely small area at the fovea and, therefore, it is here and nowhere else that a clear image must be formed—imaged sharply or not, on any other part of the retina objects appear blurred. For this narrow pencil of light, necessary to form the foveal image, only a small portion of the correcting lens is used at one time.

Thus, if the eye were immovable, so that the relative position of the lens before it were unchanged and only a small portion at the center of the glass constantly utilized, the combination of an eye and its correcting glass would differ from nearly every other optical instrument in that none of the ordinary aberrations need be considered. Any type of lens having the proper dioptric power in the utilized portion would be satisfactory. But the eye continually moves around in the orbit and as it turns and looks through the periphery of the lens there is, besides other changes, a certain amount of blurring of the image due to the astigmatism of oblique pencils of light. This is the only aberration in an ophthalmic lens that is serious enough to require special attention and one which, fortunately, can be eliminated in a single piece of glass.

A convex surface produces a certain type of astigmatism of oblique pencils, which will be neutralized by an opposite type of astigmatism by a concave surface. The proper combination of convex and concave surfaces can be found by a tedious and complicated process for each particular lens power, so that the aberration of one surface will neutralize that of the other. The result is always a deep curved type of lens.

Provided the distance between a lens of required power and the center of rotation of the eye is known, and also the thickness of the glass, and the distance of the object viewed, the astigmatism of oblique pencils

of light can be corrected out almost to the rim of an ordinary spectacle lens by giving the lens a certain curvature or front-back combination of powers. (For example, disregarding certain small differences, a convex lens of 2 diopters may be bent from the flattest form—1 diopter on each side—through a plano on one side and +2 on the other, —2 on one side and +4 on the other, to —6 on one side and +8 on the other, and so forth, within limits, as long as the algebraic sum of the powers of the two sides equals +2.) This type of lens, the purpose of which is to minimize the astigmatism of oblique pencils, is generally known as a point focal, wide angle or corrected lens.

Tscherning in 1908 constructed a graph giving the various combinations of front and back surfaces which, when given to lenses, will correct out the astigmatism of oblique pencils within a solid angle of 60 degrees for powers ranging from —20 to +7 diopters.

To be exact, the lens must be constructed for a fixed object distance and if the calculation is made for an object placed at infinity, which is usually the case, the lens will be theoretically inaccurate for every other distance. That is to say that, for the same person, the lens designed for distant vision will have an entirely different colexure from that designed for the reading distance. This means that it is absolutely impossible to correct out the astigmatism of oblique pencils in both the distance and reading portions of bifocals. One or the other must be wrong. In order to produce a perfect wide angle or point focal lens, therefore, it would be necessary to have a different combination of surfaces for every dioptric power and for every object distance. To accomplish this, the power of each surface would need to run into three or more decimal places. Surfaces so accurate cannot be ground and, furthermore, it is impracticable from the standpoint of the manufacturer to grind different curves for every power; nor is this necessary for the requirements of an ophthalmic lens. An ophthalmic lens need only be approximately correct for practical purposes, especially in the low powers, since very small astigmatic errors as well as other aberrations are easily ignored by a healthy eye.

Those having any knowledge of the literature of geometric optics know that practically nothing of what has been stated here is new. Deeply curved or meniscus lenses were mentioned by Kepler as early as 1604 and recommended by Hertel in 1716. Toric lenses were ground by Anton Wagner in Philadelphia fifty years ago. Although the theory of wide angle lenses has been known for a great many years, certain manufacturers imply in their advertisements that they have made a new discovery and that they, and only they, have the ideal ophthalmic lenses—corrected to the very edge for both the error of marginal focal power and the astigmatism of oblique pencils, even in bifocals. No one knows better than they that this is not true. What is most glaring is that while no two of the many patented forms are alike, each is claimed to be perfect. As a matter of fact, a lens of this kind is a compromise at best and any one is just about as good as another—and no more comfortable to the average glass wearer than the series of lenses that I have suggested in several previous articles.

The following paragraph from the patent papers of one of the largest advertisers of wide angle glasses will show what has really been accomplished by the lens designers of most manufacturers and is much more in keeping with the truth than anything they care to state

1. The Committee on Standardization of Instruments and Drugs is composed of Dr. Sanford R. Gifford, chairman, Dr. Francis Heed Adler, Dr. Clifford Walker, Dr. Jonas Friedenwald and Dr. John MacNée.

in their advertising copy: "Always keeping in mind the commercial production of the various powers of lenses so that the same shape surfaces may be used for as many different power lenses as possible within limits of marginal error."

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

DIPHThERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1934, p. 393).

Parke, Davis & Company, Detroit.

Diphtheria Toroid, Alum Precipitated (Refined)-P. D. & Co.—Prepared by detoxifying diphtheria toxin of 0.1 L+ dose with a 0.4 per cent solution of formaldehyde, adding to the resultant toxoid sufficient potassium aluminum sulphate to make a solution of 2 per cent, washing the precipitate with physiologic solution of sodium chloride and suspending in a sufficient amount of physiologic solution of sodium chloride to bring it back to the original volume. The finished product is preserved with sodium ethyl mercuric-thiosalicylate 1:10,000 (Merthiolate). It is standardized according to the requirement of the National Institute of Health: guinea pigs weighing 500 Gm. given one human dose must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood.

Marketed in packages of one 1 cc. vial and in packages of one 10 cc. vial containing one and ten doses, respectively.

DEXTROSE (See New and Nonofficial Remedies, 1934, p. 270).

The following dosage forms have been accepted

Ampules Solution Dextrose (d-Glucose) U. S. P., 10 Gm., 20 cc.: Each ampule contains dextrose-U. S. P., 10 Gm., in distilled water to make 20 cc.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y.
Ampules Solution Dextrose (d-Glucose) U. S. P., 25 Gm., 50 cc.: Each ampule contains dextrose U. S. P., 25 Gm., in distilled water to make 50 cc., and is accompanied by an ampule containing 2 cc. of a buffer solution composed of dibasic sodium phosphate, 0.3 Gm., and monobasic potassium phosphate, 0.024 Gm., in distilled water.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y.
Ampules Solution Dextrose (d-Glucose) U. S. P., 50 Gm., 100 cc.: Each ampule contains dextrose U. S. P., 50 Gm., in distilled water to make 100 cc. and is accompanied by an ampule containing 4 cc. of a buffer solution composed of dibasic sodium phosphate, 0.6 Gm., and monobasic potassium phosphate, 0.048 Gm., in distilled water.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y.
Ampules Solution Dextrose (d-Glucose) U. S. P., 25 Gm., 50 cc. (Buffered): Each ampule contains dextrose-U. S. P., 25 Gm., in distilled water to make 50 cc. The solution is buffered with sodium citrate 0.25 per cent.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y.
Ampules Solution Dextrose (d-Glucose) U. S. P., 50 Gm., 100 cc. (Buffered): Each ampule contains dextrose U. S. P., 50 Gm., in distilled water to make 100 cc. The solution is buffered with sodium citrate 0.25 per cent.

Prepared by the Cheplin Biological Laboratories, Inc., Syracuse, N. Y.

UCOLINE COD LIVER OIL CONCENTRATE.—

The unsaponifiable fraction of cod liver oil, prepared by the Marcus process, dissolved in a bland mineral oil. Each gram of the solution contains 5,500 U. S. P. X (1925) units of vitamin A and 1,800 A. D. M. A. units of vitamin D (according to the U. S. P. X, Revised, 1934, 7,700 units of vitamin A and 492 units of vitamin D).

Actions and Uses.—Ucoline Cod Liver Oil Concentrate possesses properties similar to those of cod liver oil so far as these depend on the fat soluble vitamin content of the latter.

Dosage.—From 3 to 6 drops of the concentrate solution three times daily (a glass dropper is included in the marketed package, designed to deliver one minim per drop); for the tablets, 1 to 2, three times daily.

Manufactured by the Ucoline Products Company, Chicago, under U. S. patent 1,690,091 (Oct. 30, 1928, expires 1945). No U. S. trade mark.

Ucoline Cod Liver Oil Concentrate Tablets—Each sugar coated tablet contains 0.02 Gm. of the dry concentrate. They are assayed to contain in each tablet not less than 1,000 U. S. P. X (1925) units of vitamin A and not less than 500 A. D. M. A. units of vitamin D (according to the U. S. P. X, Revised, 1934, 1,400 units of vitamin A and 150 units of vitamin D). This represents 1,790 U. S. P. X (1925) units of vitamin A (2,506 U. S. P. X, Revised, 1934), and 895 A. D. M. A. units of vitamin D (276 U. S. P. X, Revised, 1934) per gram of tablet.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

YEAST VITAMIN-HARRIS TABLETS AND BREWER'S YEAST-HARRIS, MEDICINAL, NOT ACCEPTABLE FOR NEW AND NONOFFICIAL REMEDIES

Yeast Vitamin-Harris Tablets and Brewer's Yeast-Harris, Medicinal, are among the vitamin preparations marketed by the Harris Laboratories, Tuckahoe, N. Y. (Isaac F. Harris, Ph.D., director). Recently these products have been widely advertised to the medical profession directly, and to the public indirectly, for a pretentious array of diseases and disorders, many of which are listed on the label and in the advertising.

Full-page advertisements have appeared in medical journals in which the product was referred to as having been

"... successfully used and prescribed in anemia, herpes infection, pellagra, ulcers, arthritis and diabetes."

The same claims appear on the folder that accompanied the trade package.

The claim that vitamin B may be used successfully in the treatment of diabetes is unwarranted. Diabetes represents, in part at least, a deficient activity on the part of the islands of Langerhans in the production of the metabolic hormone insulin. There is no evidence in all the extensive literature on diabetes that has been developed since the discovery of insulin that it (insulin) can be produced in any other manner or in any other place than by and in the islands of Langerhans of the pancreas. Nor has it been proved conclusively that there is any other drug, product or chemical compound having even a remotely similar effect on the blood sugar level. Further, there is lack of evidence that yeast, vitamin B, or any other known vitamin has any effect on the faulty dextrose utilization in uncomplicated diabetes.

The claim that yeast is effective in the treatment of pernicious anemia appears to be an obvious misinterpretation of known facts and published data. It has been shown (Castle and others) that autolyzed yeast and other substances containing the vitamin B complex, when mixed with normal gastric juice, may produce a reticulocytosis in patients with pernicious anemia. Although in a rare case autolyzed yeast alone may have some effect, yeast by itself must be considered ineffective and cannot be recommended as such in pernicious anemia. It may be of distinct value in certain other types of macrocytic anemia. However, in all such types of macrocytic anemia liver and stomach preparations are effective. In the macrocytic anemia of pregnancy in India, Wills has shown that autolyzed yeast is effective. Similarly, Castle and Rhoads have found autolyzed yeast effective in certain patients with sprue. The facts at present available indicate that the active agent in autolyzed yeast is not to be identified with any designated portion of the vitamin B complex, although this was the tentative suggestion of Castle and Strauss. Nor is there evidence that in Addisonian pernicious anemia any vitamin product by itself has a specific effect (such as is claimed for Yeast Vitamin-Harris) in increasing the reticulocyte count and restoring a normal blood picture. The only clinically proved indications at the present time for the use of vitamin B (and its related fractions) lie in the so-called deficiency diseases of beriberi, polyneuritis and, probably, pellagra.

The attempt of the Harris Laboratories to sell its products (as "useful and successful agents" in two such grave diseases as diabetes mellitus and pernicious anemia) by advertising in the medical journals is not a compliment to the intelligence of the medical profession. The conscientious practitioner would do well to adhere to the established armamentarium in combating such serious conditions as diabetes and pernicious anemia. Insulin and liver and stomach preparations are proved, whereas yeast has only the claims of a manufacturer to recommend it.

Neither the Harris trade package nor the accompanying literature contains any statement of potency, nor does the Council know of any published protocols on the assay of the products as purchased on the open market.

The Council declared Yeast Vitamin-Harris Tablets and Brewer's Yeast-Harris, Medicinal, not acceptable for New and

Nonofficial Remedies because they are marketed with no statement of potency on the labels; with names of diseases for which they are recommended appearing on the label; and with exaggerated, unwarranted and misleading therapeutic claims.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

RAYMOND HFRWIG, Secretary

NOT ACCEPTABLE

CURTISS MILK NUT LOAF

The Curtiss Candy Company, Chicago, submitted to the Committee on Foods a chocolate enrobed candy containing corn syrup, sucrose, roasted peanuts, coconut butter, gelatin, glycerin, tapioca starch, vanillin and coumarin

Analysis (submitted by manufacturer).—

	per cent
Moisture	57
Ash	0.6
Fat (acid hydrolysis method)	20.5
Protein (N X 6.25)	6.2
Reducing sugars as dextrose	10.6
Sucrose (copper reduction method)	32.5
Crude fiber	0.7
Carbohydrates other than crude fiber (by difference)	66.3

Discussion of Name.—The name "Milk Nut Loaf," signifying that milk is an important ingredient, is deceptive as to the composition and nutritional values of the candy, in that milk is not a component. Descriptive names for foods should be truthfully informative. Good advertising is not possible without correct and appropriate names for foods.

The company was informed of the criticisms of the Committee but for business reasons is unwilling to correct the name. The candy will therefore not be listed among the accepted products of the Committee on Foods.

ACCEPTANCES WITHDRAWN

APPROVAL TOMATO JUICE

Distributor.—M. E. Horton, Inc., Washington, D. C.

CALIFORNIA FRUIT GROWERS EXCHANGE ADVERTISING FOR SUNKIST ORANGES, LEMONS AND GRAPEFRUIT

Sponsor.—California Fruit Growers Exchange, Los Angeles

CEDAR HILL BRAND TOMATO JUICE

Distributor.—Hassendeubel Grocery Company, St. Louis

COMET BROWN RICE

COMET BROWN RICE FLAKES

Manufacturer.—Comet Rice Company, New York.

EVER READY BISCUIT FLOUR (PREPARED)

Manufacturer.—F. M. Brown's Sons, Sinking Springs, Pa.

HARDY'S TWIN LOAF BREAD

Manufacturer.—Hardy Baking Company, Flint, Mich.

HORLICK'S MALTED MILK LUNCH TABLETS (PLAIN AND CHOCOLATE FLAVORED)

Manufacturer.—Horlick's Malted Milk Corporation, Racine, Wis.

JEWEL COCOA

JEWEL EXTRA FANCY HEAD

BLUE ROSE RICE

Distributor.—Jewel Tea Company, Inc., Barrington, Ill.

LAUB'S QUALITY BREAD

Manufacturer.—The Jacob Laub Baking Company, Cleveland

LONG ROYAL BREAD

ROYAL TABLE QUEEN BREAD

Manufacturer.—Royal Baking Company, Ogden and Salt Lake City, Utah.

MEYERS CORN SYRUP WITH CANE FLAVOR

Distributor.—Meyers, Walnut Ridge, Ark.

MITY GOOD BRAND GOLDEN TABLE SYRUP

Distributor.—Fox River Grocery Company, Appleton, Wis.

MOTHER'S JUMBO BREAD

Manufacturer.—M. Erickson Bakery Company, Inc., LaCrosse, Wis.

MURI BRAND TOMATO JUICE

Distributor.—New England Importation Corporation, Boston.

NEW STATE BRAND TOMATO JUICE

Distributor.—The Williamson-Halsell-Frazier Company, Oklahoma City.

N. J. C. PURE FOOD BRAND JUICE OF FANCY WHOLE TOMATOES

N. J. C. PURE FOOD BRAND PANCAKE SYRUP

N. J. C. PURE FOOD BRAND FANCY WHITE SYRUP

Distributor.—Northern Jobbing Company, Chicago and St. Paul.

PORTAGE BRAND GOLDEN CORN SYRUP WITH CANE FLAVOR

PORTAGE BRAND CRYSTAL WHITE SYRUP
Distributor.—Portage Wholesale Company, Portage, Wis.

SAMOS BRAND WHITE CRYSTAL SYRUP

Distributor.—Samos Wholesale Grocery Company, Cleveland

STROEHMANN'S KEW BEE BREAD

STROEHMANN'S MILK BREAD

Manufacturer.—Stroehmann Brothers Company, Harrisburg, Pa.

USEMORE BRAND GOLDEN SYRUP

USEMORE BRAND WHITE TABLE SYRUP
Distributor.—Service Grocer Company, Detroit.

WALDENSIAN TAR HEEL BREAD

Manufacturer.—Waldensian Baking Company, Valdese, N. C.

YACHT CLUB BRAND CORN SYRUP WITH CANE FLAVOR

Distributor.—Bemis, Hooper, Hays Company, Oshkosh, Wis.

Acceptances Withdrawn.—The sponsors of the listed previously accepted foods are not willing to furnish the Committee with copy of all pieces of new advertising or to inform the Committee of changes in the composition of the products in accordance with the requirement of its amended Rules and Regulations. This material and information are necessary to assure the Committee that the conditions of acceptance of the products and the advertising are being fulfilled. The requirement is essential to the maintenance of the standards of food composition and advertising as expressed in the Rules and General Decisions of the Committee. There is no apparent justifiable reason why the sponsor of an accepted food who is manufacturing or distributing a wholesome product of full nutritional value and is using truthful and proper advertising should not be willing to agree to inform the Committee of changes in composition of the food and furnish copy of all pieces of advertising, involving only nominal expense and time.

Since the sponsors of the listed accepted foods are not willing to comply with this simple requirement to assure that the products and the advertising are being maintained acceptable, acceptance has been withdrawn.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

SATURDAY, NOVEMBER 3, 1934

THE NATURE OF ANTIBODIES

The question of the nature of antibodies is of practical as well as theoretical importance. The more complete the knowledge of their nature, the more favorable the conditions for preparing them for therapeutic and diagnostic use. Insight into the mechanisms of immunity is dependent in large measure on an understanding of the composition and structure of antibodies. Many attempts have been made to separate the antibodies from the other constituents of serum. On variation in the salt concentration of serum the antibodies in general come down with the globulin fraction no matter what method is used, and as a rule antibodies are not associated with or limited to any particular form of globulin thus prepared. The methods now in use for the concentration and purification of diphtheria and other antitoxins are based on the salt precipitation of serum globulins. Under the proper conditions, alcohol precipitates proteins as well as antibodies without any damage to the latter, so long as the proteins are not denatured in the process. By precipitation in low salt concentration as well as with alcohol, the specific antibodies in antipneumococcus horse serum can be secured in relatively high purity in a fraction of the serum globulin. On adsorption by aluminum hydroxide and other substances as well as on cataphoresis, the antibodies appear to remain in association with the globulin.

Since antibodies form specific combinations with antigens, many efforts have been made to recover the antibody from the antigen-antibody compound; e. g., agglutinins from agglutinated bacteria or red corpuscles. In the experiments of this category, those dealing with the antigenic polysaccharides of pneumococci, which can be prepared free from protein, and antipneumococcus horse serum, appear to have yielded the best results. This antigen-antibody precipitate can be washed free from the inactive proteins in the horse serum and then the antibody protein in the precipitate can be dissociated by alkaline solution. Without going into details, let it suffice to say that Felton¹ has recom-

bined the antibody protein and the antigen into the original complex. Felton concludes that the antibodies in his antipneumococcus horse serum are of protein nature. This conclusion is in full harmony with the outcome of the attempts so far to prepare antibodies in pure form from antiserum; namely, that they cannot be separated from proteins. Heat, alcohol, organic solvents and other factors that alter or denature proteins also change or destroy the peculiar properties of proteins. When specific precipitin serum is added to a serum containing agglutinin or antitoxin, the agglutinin or antitoxin is removed in the resulting precipitate; in the case of diphtheria, antitoxin diphtheria toxin is bound by such a precipitate.

Further evidence of the protein nature of antibodies is furnished by the precipitate in the specific precipitin reaction. This precipitate contains more protein than can be derived from the antigen used in the reaction; in fact, the precipitate consists largely of globulin from the antiserum. When bacteria or red corpuscles are acted on by specific antiserum they conduct themselves in an electric field as if coated by a layer of globulin, and the globulin or protein attached to particulate antigens in these and similar experiments has been shown by immunologic reactions to be the same as that in the antiserum. Quantitative tests point to this globulin as the actual antibody. Marrack² concludes a thorough and detailed report of the work on the nature of antibodies with the statement that according to their properties antibodies "consist of modified serum globulin," the antibody molecules differing from the normal globulin molecules either by rearrangement in structure or by the presence of a prosthetic group, which gives them the power to combine with antigen.

HETEROTOPIC INTESTINAL MUCOSA AS A POSSIBLE FACTOR IN THE GENESIS OF GASTRIC ULCER

The occurrence of heterotopic intestinal mucosa in the mucous membrane of diseased stomachs has been known for some time. It has been found in cases of chronic gastritis, carcinoma, achylia and pernicious anemia. Most observers regard it as an instance of metaplasia arising on a basis of an inflammatory process. This theory found its support in the fact that heterotopic islands of intestinal mucosa occurred with greatest frequency in chronic atrophic gastritis and only rarely in normal stomachs. According to this view, defects in the gastric mucosa resulting from an inflammatory process permit the growth of a new and indifferent epithelium, which may later differentiate into the type resembling intestinal epithelium. The regeneration is therefore of a faulty, atypical kind rather than a true metaplasia. Moszkowitz³ in fact designated it

1. Felton, L. D.: Pneumococcus Antibodies—What Are They? Science 79: 277 (March 23) 1934.

2. Marrack, J. R.: The Chemistry of Antigens and Antibodies, Medical Research Council, Special Report Series, No. 194, London, 1934.
3. Moszkowitz: Zur Pathologie des ulcusbereiten Magens, Arch. f. klin. Chir. 122, 1922.

as "indirect metaplasia." This view was shared by Lubarsch, Faber, Heyrovsky and, more recently, by Puhl, Stoerck, Konetzny and others.

The recent report by Clar² from Schloffer's clinic in Prague is interesting because it offers observations that seem to refute the correctness of the metaplastic theory. Clar views this heterotopic tissue not as a metaplasia but as a true congenital displacement. In their relation to the gastric juice these heterotopic islands of intestinal mucosa constitute a *locus minoris resistentiae* and therefore a possible factor in the genesis of the gastric ulcer. In an examination of fifteen fetuses, Clar found intestinal mucosa regularly present in the stomachs of fetuses up to the seventh month. The frequency of the occurrence diminishes with increase in age. Thus, in three full term infants this condition was present in only one. In twelve cadavers whose histories do not mention gastric disease and in twenty-six gastric specimens resected for the cure of a duodenal ulcer this heterotopy was not found once. Apparently these displacements tend to disappear with further growth of the individual because of the comparatively weaker growth than that of the environmental tissues. Clar found such islands in six out of ten gastric specimens resected for gastric ulcer and in one out of three specimens resected for a pyloric ulcer. It is noteworthy that these elements were found not only in the immediate neighborhood of the ulcer but in other parts of the stomach as well, sometimes as far as 10 cm. away from the ulcer. The tissue in question was surrounded by a normal gastric mucosa. It varied in size from a single crypt, or a few crypts, to circular formations 4 by 5 mm. in diameter. Their epithelium, according to Clar, resembled that of intestinal mucosa in every characteristic. There were to be seen the columnar cuticular cells, goblet cells, Paneth's cells and chromaffin cells. Clar failed to find evidence of a chronic gastritis in any of his cases. As congenital displacements these islands bear comparison with islands of gastric mucosa found in the esophagus and in Meckel's diverticulum, and with islands of pancreatic tissue found in the stomach wall. The author admits the far more frequent occurrence of heterotopic intestinal mucosa in the stomachs the seat of a pathologic process, particularly of chronic atrophic gastritis, but believes that the intestinal epithelium covering these defects was derived from a preexisting intestinal epithelium which proliferated under the stimulus of inflammation.

Müller³ called attention to developmental disturbances as a possible basis for the formation of a gastric ulcer. He pointed out that, when an ulcer develops in a Meckel's diverticulum containing gastric mucosa, the

initial peptic damage is seen most frequently not in the gastric tissue but in the intestinal tissue. This localization speaks for a direct peptic damage of the exposed intestinal mucosa by the secretion of the adjacent gastric mucosa. While unanimity is absent on the question of whether the intestinal mucosa can be digested by the gastric juice, the author feels that Buchner's answer in the positive is sufficiently supported by facts to be accepted. The latter points to the case of an ulcer in Meckel's diverticulum, to the well known postoperative jejunal ulcer of a gastro-enterostomy, and to the ulcer in the Mann-Williamson animal experiment. It appears, therefore, that heterotopic islands of intestinal mucosa occurring in the gastric mucosa constitute a *locus minoris resistentiae* and as such may play a part in the genesis of the gastric ulcer. Its rôle perhaps is the creation of the primary defect in Aschoff's sense. The primary defect or erosion may develop further in the presence of other factors favoring an inflammatory-ulcerative process.

Regarded in the light of J. Bauer's concept, a congenital displacement of the kind that has been discussed confers a predisposing constitutional inferiority on the stomach containing it. The localization of this heterotopic tissue in the pyloric, prepyloric and lesser curvature areas explains, in accordance with the mechanical-functional factors elucidated by Aschoff and K. H. Bauer, the failure on the part of the primary defect or erosion to heal.

The heterotopic islands of intestinal mucosa found in the stomach the seat of gastritis or of an ulcer is therefore not the result of the existing pathologic condition but its cause. This adds another theory to some forty already existing, which attempt to elucidate the genesis of the gastric ulcer.

ARTIFICIAL FEVER THERAPY

The limitations for the use of artificial fever therapy are becoming more clearly defined. A recent report of Simpson¹ is based on the use of the Ketting hypertherm, a simple air conditioned cabinet with which it is possible to elevate the patient's temperature rapidly and to maintain it at the desired level for an extended period. The use of this form of hyperpyrexia has been largely concentrated on syphilis. One hundred and seventeen syphilitic patients were treated, and in eighty-seven the course was completed. The best results were obtained by combining antisyphilitic therapy (e. g., bismuth compounds, iodobismutol or tryparsamide) with at least fifty hours of sustained fever at approximately 106 F. The sessions of fever were usually given weekly for ten weeks, with five hours of sustained fever at each session. The anti-syphilitic drug was injected half an hour before each session of fever. After completion of this program

2. Clar, Fritz: Ueber Heterotopie Darm-Schleimhaut im Magen und ihre Bedeutung für die Ulcusgenese, Beitr. z. klin. Chir. 160: 145-160 (No. 2) 1934.

3. Müller, P. F.: Ueber das Ulcus pept. perforans des persist. Meckelsches Divertikel und seine Verwandtschaft mit dem Ulcus Ventriculi, Beitr. z. klin. Chir. 115: 560, 1919.

the patients were given a follow-up course of anti-syphilitic chemotherapy at weekly intervals for twenty weeks.

Of sixteen patients with dementia paralytica, twelve obtained complete clinical remission, two improved markedly and were restored to a working status, one showed moderate improvement, and one was unimproved. The spinal fluid Wassermann and Kahn reactions were reversed to negative in six instances, became less strongly positive in six and remained positive in three. The blood Wassermann and Kahn reactions were reversed to negative in eight, became less positive in three and remained positive in four. There were seven patients in the taboparetic group. Improvement in mental orientation occurred in six. Subsidence of root pains occurred in all, but two patients experienced recurrence of pain, which was controlled by additional treatment. In four of the five patients with ataxia, the gait improved. The spinal fluid Wassermann and Kahn reactions were reversed to negative in two instances, became less strongly positive in one and remained positive in four. The blood Wassermann and Kahn reactions were reversed to negative in one, became less positive in one, remained positive in two, remained negative in three and became more strongly positive in one. One patient in this series had a syphilitic neuroretinitis, which responded promptly to the treatment.

Of nine patients with tabes dorsalis, ataxia was a prominent symptom in eight; two were restored to a normal gait, two showed 50 per cent improvement, two showed 75 per cent improvement and two were not improved. Root pains were abolished in all. In one patient the symptoms of cord bladder disappeared. The spinal fluid reactions were reversed to negative in two, became less strongly positive in three and remained positive in four instances. In a group of ten patients with diffuse central nervous system syphilis with eye symptoms predominating, favorable results were promptly obtained in six with interstitial keratitis, two with choroiditis, one with neuroretinitis and one with iritis. In six patients with asymptomatic neurosyphilis, the spinal fluid Wassermann and Kahn reactions of all were reversed to negative. There were six so-called blood Wassermann-fast cases. The serologic reactions were reversed to negative in three, became less strongly positive in two and remained positive in one.

Simpson reports some studies on the use of this treatment in early syphilis and in arthritis. He believes that in early syphilis the results are often favorable, though there has been insufficient observation from which to draw conclusions. The problem in arthritis appears to be one of selection of the proper type of patients. In the hands of unskilled workers, he believes, the possibility of doing harm with this form of therapy is perhaps greater than that of doing good. Its use should therefore be confined for the present to those having an intimate knowledge of the subject.

Current Comment

NOBEL PRIZE AWARDS IN MEDICINE

The Nobel prize in medicine for 1934 was awarded last week to three physicians of the United States: Drs. George R. Minot and William P. Murphy of Boston and Dr. George H. Whipple of Rochester, N. Y. The sum to be awarded is reported to be \$41,000. The research leading to the present clinical use of liver in pernicious anemia has been repeatedly reviewed in these columns. Many of the significant studies appeared first in *THE JOURNAL*. Briefly, Whipple and his associates showed that certain foods, especially liver, will induce rapid regeneration of blood in dogs made anemic by bleeding. Thereafter, Minot and Murphy applied the method clinically, made controlled studies in the hospital, and published their most significant early paper in *THE JOURNAL* in August 1926. One may, as is usual in such cases, find occasional references to the use of liver in the diet as far back as the published literature of medicine goes, but the prize is awarded to the investigators mentioned because of their establishment by scientific methods of facts that have led to the almost universal use of their suggestions in the treatment of the anemias. The story of the anemias, as Dr. Whipple modestly remarked when informed of the award, is far from finished and the work must go on. Like other new conceptions in the field of medicine, the new phase in the treatment of pernicious anemia has opened up a great land of promise for investigators of the blood in health and in disease. The deficiencies of leukocytes, of thrombocytes and of various chemical constituents of the blood offer a great opportunity for further study. When one realizes how far we have progressed since 1920 in relationship to our knowledge of the blood and its disorders, the hope for the future is greatly enhanced. By such awards as the Nobel prize, civilization pays some part of its debt to the accomplishments of medical science. That debt is already so great, however, that it can never be fully repaid. Yet the medical scientist has asked but little in the way of recompense for his efforts; he merely hopes to continue at his work without the obstructions of unenlightened interference from political or commercial sources.

EFFECTS OF TOBACCO SMOKING

The possible important physiologic effects of tobacco smoking have been investigated from several angles. Recently Dill, Edwards and Forbes¹ reported on the relation of smoking to blood sugar, blood lactic acid and metabolism. The subjects for their experiments remained at rest in the fasting state for ninety minutes before smoking and for forty-five minutes afterward. Each subject smoked one cigaret, inhaling the smoke during a period of from five to ten minutes. Capillary blood was obtained twice before smoking, one or more times during smoking, and frequently during the sub-

1. Dill, D. B.; Edwards, H. T., and Forbes, W. H.: Tobacco Smoking in Relation to Blood Sugar, Blood Lactic Acid and Metabolism, *Am. J. Physiol.* 109: 118 (July) 1934.

sequent forty-five minutes. Three samples of venous blood were also obtained. The sugar determinations were made by the micro method of Folin and Malmros. In addition to observations made on ten subjects in the fasting state, similar experiments were carried out on two subjects beginning about three hours after a light breakfast. They concluded that smoking one cigaret produced no change in blood sugar, lactic acid or respiratory quotient. In regard to oxygen consumption, however, there appeared to be significant alterations subsequent to smoking. While the oxygen consumption after smoking may remain unchanged in some subjects, in others it may increase as much as 10 or 15 per cent. Although this increase is of small magnitude and of doubtful general importance, it does indicate that subjects for basal metabolic rate testing should not smoke in the morning during which the test is to be made.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

- November 8. Your Child's Sleep.
- November 15. The Health Audit.
- November 22. Eat, Drink and Be Merry.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

- November 6. The Fight Against Appendicitis, W. W. Bauer, M.D.
- November 13. Does Medicine Cost Too Much? Morris Fishbein, M.D.
- November 20. The Doctor of Tomorrow, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Society News.—At a meeting of the Tuscaloosa County Medical Society at Bryce Hospital, Tuscaloosa, October 15, members of the staff presented the program. Drs. James S. Tarwater and Frank A. Kay discussed dementia praecox, and Dr. Toombs Lawrence exhibited cases of paranoia. Dr. Thomas K. Lewis, Birmingham, addressed the society in September on treatment of heart block.

University News.—Dr. James S. McLester, professor of medicine, University of Alabama School of Medicine, and President-Elect, American Medical Association, delivered the annual Gorgas address before the La Fayette Guild Chapter of the Gorgas Medical Society at the university, October 3. The occasion was in commemoration of the eightieth anniversary of the birth of William Crawford Gorgas. Dr. Allan Walker Blair has resigned as associate professor in pathology and bacteriology to accept a surgical appointment in the Winnipeg General Hospital, and Dr. James B. McLester, Birmingham, has been appointed clinical assistant in medicine at the university.

DELAWARE

Society News.—Dr. Temple S. Fay, Philadelphia, addressed the New Castle County Medical Society, October 16, on "Neurologic Signs in General Practice." Dr. Fay is professor of neurosurgery in Temple University School of Medicine. Dr. Fielding H. Garrison, Baltimore, discussed "English Medicine and Anglo-Saxon Life" before the society, September 18.

State Medical Meeting and Election.—Dr. Jerome D. Niles, Townsend, was elected president of the Medical Society of Delaware at its annual meeting in Dover, October 9-10. Vice presidents elected are Drs. Joseph B. Waples Jr., Georgetown, and Clarence J. Prickett, Smyrna. The next annual meeting will be held in Wilmington in October. The scientific program included, among others, the following speakers:

- Dr. Joseph S. McDaniel, Dover, The History and Progress of Medicine.
- Dr. Joseph P. Wales, Wilmington, A Preliminary Report on Tuberculosis Prevention in Delaware.
- Dr. Robert W. Tomlinson, Wilmington, Gastro-Intestinal Disease: Some Recognized Essential Diagnostic Procedures.
- Dr. Lay Martin, Baltimore, Recent Investigations on the Physiology of Gastric Secretion and Its Relation to Clinical Medicine.
- Dr. Henry D. Jump, Philadelphia, Treatment of Pneumonia by Means of Serum, Oxygen Tent and Pneumothorax.
- Dr. P. Brooke Bland, Philadelphia, Intracranial Injuries of the New-Born from the Standpoint of the General Practitioner.
- Hon. Daniel J. Layton, chief justice of Delaware, Medicolegal Problems.
- Dr. Charles E. Wagner, Wilmington, Pyelitis in Children.
- Dr. John B. Baker, Milford, Infant Feeding, with Special Reference to Lemon Feeding.
- Dr. George C. McElfatrick, Wilmington, Results of High Voltage X-Ray Treatment in Metastatic Carcinoma of Bones.
- Dr. Douglas M. Gay, Wilmington, Prevention and Cure of Cancer.
- Dr. Emil R. Mayerberg, Wilmington, Nasal Accessory Sinuses from the Standpoint of the General Practitioner.
- Dr. William Bates, Philadelphia, Faulty Body Mechanics a Factor Causing Diagnostic Errors.

ILLINOIS

Society News.—Speakers before the St. Clair County Medical Society in East St. Louis and Belleville in October were, respectively, Drs. Ellis Fischel and Clinton W. Lane, St. Louis, on "Cancer of the Breast" and "Skin Diseases in General Practice," respectively.

Silver Nitrate Not Being Used.—The Illinois State Department of Health calls attention to the fact that silver nitrate solution is not being used as contemplated by the law enacted last year requiring the use of this material in the eyes of all new-born children. The department furnishes this solution without cost. Four counties in the state have obtained no silver nitrate solution at all from the department this year, and nearly a dozen others have obtained only insignificant amounts.

Chicago

Dr. Lewis to Lecture at Rush.—Dr. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, will deliver the third E. R. DeBoth Memorial Lecture at Rush Medical College, November 6, at noon. His subject will be "The Story of the Hypophysis."

Personal.—Dr. Aaron Arkin has been promoted to associate clinical professor of medicine at Rush Medical College. —Prof. David Adlersberg of the University of Vienna lectured at Mount Sinai Hospital, October 22, and at the Cook County Graduate School of Medicine, October 23, on "The Dietetic Management of Diabetes."

Lay Educational Program.—The Chicago Medical Society will sponsor a lay educational program, November 14, in the auditorium of the Medical and Dental Arts Building. Speakers will be Drs. Lloyd L. Arnold, professor of bacteriology and preventive medicine, University of Illinois College of Medicine, and Logan Clendening, clinical professor of medicine, University of Kansas School of Medicine. They will discuss "You and Your Germs."

Society News.—Speakers before the Chicago Neurological Society, October 18, were Drs. Paul C. Bucy and Arthur Earl Walker, Chicago, on "Congenital Dermal Sinuses"; Isidore Finkelman and William Mary Stephens, Elgin, Ill., "Dinitrophenol in Dementia Praecox," and Dr. Walker on "Encephalography in Children." —At a meeting of the McDonagh Society for Clinical Research, October 19, Dr. Arthur Trevenning Harris, Gary, Ind., spoke on "Colitis and Its Complications." —Dr. Fred J. Taussig, St. Louis, was the guest speaker before the Chicago Gynecological Society, October 19. Other speakers were Drs. Fred L. Adair and Morris Edward Davis on "Chronic Atrophic Dermatitis of the Vulva," and Carl Henry Davis, Milwaukee, "Use of the Colposcope in the Diagnosis of Cervical Lesions." —Dr. Joseph L. Miller will address the annual meeting of the Institute of Medicine, December 24, on "The Influence of Claude Bernard's Experimental Methods on Medicine."

INDIANA

Cancer Program.—Dr Max Cutler, Chicago, will address a dinner meeting of the St Joseph County Medical Society, South Bend, November 7, on "The More Recent Developments in the Treatment of Cancer by X-Rays and Radium." This lecture is one of a series sponsored by the society which opened October 2, when Dr Marcus W Lyon Jr, South Bend, spoke on "The History and Etiology of Cancer." Dr Alfred S Giordano, South Bend, discussed "The Role of the Pathologist in the Cancer Problem," October 18, Dr Fred R Clapp, South Bend, October 23, "Cancer of the Female Reproductive Organs," and Dr James L Wilson, South Bend, "Cancer of the Gastro Intestinal Tract." Subsequent speakers, all of South Bend, will be

Drs Carroll C Hyde and Louis A Sandoz, November 13, on Cancer of the Genito Urinary Tract and Skin Cancer

Drs Slocumb R Edwards and John C Boone, November 27, Cancer of the Eye and Cancer of the Ear, Nose and Throat

Dr George T Green, December 11, Breast Tumors

Dr Robert B Acker, December 18, Bone Tumors

District Meetings.—The fifty-second semiannual meeting of the Eleventh Indiana Council District Medical Association was held at Logansport, October 17, at the Northern Indiana Hospital. Dr Franklin G Ebaugh, Denver, addressed the scientific session on "Psychotherapy in the General Practice of Medicine," and Dr Lawrence H Gilman, Indianapolis, "Meningitis." Entertainment in the evening included a banquet and minstrel show. —At a meeting of the Tenth District Medical Society in Gary, October 24, the following program was presented

Dr Claud R G Forrester, clinical professor of surgery, Loyola University School of Medicine, Chicago, Reduction of Fractures Under Local Anesthesia with Ambulatory Treatment

Dr Austin A Hayden, Secretary, Board of Trustees American Medical Association, Chicago, What the Socialization of Medicine Means to the General Practitioner

Dr Russell L Cecil, professor of clinical medicine, Cornell University College of Medicine, New York Pneumonia

Dr Robert Sonnenschein, assistant clinical professor of laryngology and otology, Rush Medical College Chicago, Practical Points of Otolaryngology for the General Practitioner

State Medical Meeting and Election.—Dr Roscoe L Sensenich, South Bend, was chosen president-elect of the Indiana State Medical Association at its annual meeting in Indianapolis, October 9-11. Dr Walter J Leach, New Albany, the incoming president, will take over his duties January 1, succeeding Dr Everett E Padgett, Indianapolis. The next annual meeting will be held in Gary. Speakers at the meeting included the following physicians

David W MacKenzie, clinical professor of urology, McGill University Faculty of Medicine, Montreal, Quebec Mechanical Factors in Renal Infections

Isidor S Ravdin, professor of surgical research, University of Pennsylvania School of Medicine, Philadelphia, Problems of Acute Appendicitis

Robert A Strong, professor of pediatrics Tulane University of Louisiana School of Medicine, New Orleans, Erythroblastic Anemia of Childhood

Emil Novak, associate in gynecology, Johns Hopkins University School of Medicine, Baltimore Endocrine Aspects of Gynecology

Lucius E Burch, professor of clinical gynecology and obstetrics, Vanderbilt University School of Medicine, Nashville, Tenn, Diagnosis and Treatment of Uterine Bleeding

Walter M Simpson, director, diagnostic laboratories, Miami Valley Hospital, Dayton, Ohio, Undulant Fever

Ralph A Fenton, clinical professor and head of the department of otolaryngology, University of Oregon Medical School, Portland Modern Views About Nasal Infections

George R Minot, professor of medicine, Harvard Medical School, Boston Some Aspects of Anemia

Sir Frederick G Banting, professor of medical research, University of Toronto Faculty of Medicine, Toronto, Silicosis

Frank H Lahey, Boston, Diagnosis and Management of Thyroid States

Dr James S McLester, Birmingham, Ala., President-Elect, American Medical Association, made an address at the annual banquet on "Borderline States of Nutritional Failure"

IOWA

Annual Clinic.—The University of Iowa College of Medicine will hold its twenty-third annual clinic in Iowa City, November 9-10. In addition to the various clinics, case presentations and laboratory demonstrations, there will be a dinner and social hour Friday evening, November 9. Dr Logan Clendenen, Kansas City, Mo., will be the speaker and discuss "Medical Subjects in Classical Art." The Purdue-Iowa football game, Saturday afternoon, will be an added attraction.

Society News.—The Bremer County Medical Society devoted its meeting in Waverly, September 20, to a symposium on socialized medicine. The speakers were Drs Charles H Graening, Waverly, Edward M Myers, Boone, Merlyn B Call, Greene, and John H Henkin, Sioux City. —Dr Ray

A Fox, Charles City, addressed the Buchanan County Medical Society in Independence, September 13, on "Treatment of Varicose Veins and Hemorrhoids by the Injection Method." —The proposed basic science law was considered by Drs Fred Moore, Des Moines, and Ransom D Bernard, Clarion before the Callhoun County Medical Society at Lohrville, September 11. —Speakers at the eighty-first anniversary meeting of the Dubuque County Medical Society, September 11, included Drs Porter P Vinson, Rochester, Minn., on "Bronchoscopic Diagnosis and Treatment of Lung Conditions", Frederick A Figi, Rochester, Minn., "Fractures of Nose, Jaws and Other Facial Bones," and Leo G Rigler, Minneapolis, "Early Diagnosis of Cancer." —Dr Jay Arthur Myers, Minneapolis addressed the Wapello County Medical Society in Wapello October 16, on "Diagnosis, Treatment and Prevention of Tuberculosis." —Dr Robert A Strong, New Orleans, will address the Linn County Medical Society, November 30, in Cedar Rapids, on "Treatment of Empyema in Children."

MAINE

Examination of Food Handlers Discontinued.—The advisory council of the state department of health and welfare rescinded the regulations relating to the examination of food handlers, September 26. According to the state medical journal, other clauses in the regulations fully take care of this problem. This action is in line with a similar plan announced by the New York City Department of Health, which in the future will stress the personal hygiene of food handlers and the entire matter of food sanitation. The health commissioner of New York stated that the cost of examination of food handlers is enormously out of proportion to the returns yielded to the people of the city.

MASSACHUSETTS

Dr. Burwell Gives Cutter Lecture.—Dr Charles Sidney Burwell, professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn., will deliver the Cutter Lecture on Preventive Medicine at Harvard Medical School, Boston, November 8. His subject will be "The Prevention or Postponement of Death from Heart Failure."

Tribute to Dr. Cushing.—A life size relief in bronze of Dr Harvey Cushing, formerly Moseley professor of surgery at Harvard University Medical School, will be presented to the medical school in November by a group of pupils, friends and associates. A bronze medallion in reduction of the original is available for those who wish a memento. The original medallion has been purchased by the Boston Museum of Fine Arts. Both the medallion and the bronze relief are the work of Paul Adrian Brodeur, Wellesley Hills. Dr Cushing is at present Sterling professor of neurology at Yale University School of Medicine, New Haven.

Mental Hygiene Survey of Teachers' Colleges.—Nine state teachers' colleges in Massachusetts were studied in a survey conducted over a two year period by Dr Henry B Elkind, medical director of the Massachusetts Society for Mental Hygiene, at the request of the commissioner of education and the presidents of the colleges. Its objectives were to ascertain the extent and method of teaching mental hygiene to learn whether the pedagogy taught maintains a mental hygiene point of view, to ascertain what is being done for the mental health of the student-teachers and for their personal development, and to offer recommendations leading to improvements of curriculum or of personnel policies. The survey was limited to a consideration of the teaching of education, educational psychology, testing, hygiene and physical and health education. The practice or training school of each college was especially observed. It was recommended, among other things, that the courses in educational psychology should be modified to include more mental hygiene content and that mental and educational tests should be given a larger place in the curriculum.

MINNESOTA

Personal.—Dr Charles Dexter Lufkin, Northfield, has been named assistant professor of health and physical education for men and physician in the college health service at Carleton College.

Society News.—Speakers before the Scott-Carver County Medical Society at Montgomery, September 11, were Drs Walter A Fansler, Minneapolis, on "Treatment of Hemorrhoids," and Myron O Henry, Minneapolis, "Complications of Elbow Fractures." —At a meeting of the Hennepin County Medical Society, September 25, speakers were Drs Chauncey

A McKinlay, on "Dimitrophenol in the Treatment of Obesity," and Willis H Thompson, "Influence of Certain Salts on Glucose Metabolism and Blood Pressure in Young Diabetics" —At a meeting of the Minnesota Academy of Medicine, October 10, Drs Samuel E Sweitzer and Carl W Laymon, Minneapolis, discussed "Multiple Areas of Cutaneous Gangrene Following Scarlet Fever," and Waltman Walters and Gerald T Church, Rochester, "Gastritis, a Phenomenon of Pyloric Obstruction, and Its Relation to Duodenal Ulcer"

MISSOURI

Personal.—The Southwestern Branch of the American Urological Association dedicated the program of its fourteenth annual meeting in St Louis, October 22-24, to Dr Bransford Lewis, St Louis, in honor of his fiftieth year in the practice of urology. A formal banquet was also held in his honor. A graduate of Missouri Medical College, 1884, Dr Lewis is emeritus professor of urology at St Louis University School of Medicine.

Midwife's License Again Revoked.—The license of Mrs Mary Ann Elizabeth Murphy, St Louis, to practice midwifery was revoked by the state board of health, September 13, on charges of "dishonest and unprofessional conduct," newspapers reported. It was the first time the board has heard charges against a midwife since 1906, in that year Mrs Murphy's license was revoked on charges of sending obscene matter through the mails. However, her license was restored in 1917. According to the reports, the complaint specifically charged Mrs Murphy with conducting a maternity home without a license, with performing four illegal operations, and with failure to file a birth certificate within ten days after a birth.

Society News.—Members of the staff of the University of Missouri School of Medicine, Columbia, offered the program of the St Louis Medical Society at its meeting, October 16. Drs Dan G Stine, professor of medicine, spoke on "The Prognostic Value of Leukocyte Counts in Pulmonary Tuberculosis," Milton D Overholser, associate professor and chairman, department of anatomy, "Recent Theories Concerning the Relationship of Hormones to Certain New Growths," Claude R Bruner, associate professor of ophthalmology and otology, "Present Status of Endoscopy," and Charles W Greene, Ph D, professor of physiology and pharmacology, "New Experimental Evidence of the Nerve Control of the Coronary Circulation and Its Significance in Clinical Cardiology." —At a meeting of the St Louis Neuropsychiatric Society, October 22, Dr Paul E Kubitschek discussed "Reading Disabilities, Etiology, Complications and Treatment." —Dr Edward A Schumann, Philadelphia, will present a review of ectopic pregnancy before the Kansas City Academy of Medicine, November 16. —Speakers before the Jackson County Medical Society in Kansas City, October 9, were Drs John L Myers on physical therapy, and Vincent T Williams on cardiac hazard of gallbladder surgery.

NEBRASKA

Society News.—Speakers at the meeting of the Omaha-Douglas County Medical Society, October 9, presented a symposium on the thyroid gland, as follows: Drs Raymond L Traynor, Maine C Anderson, Augustus D Cloyd, James F Kelly and Nymphus F Hicken. —Drs Samuel F Haines and Alfred W Adson, Rochester, Minn, addressed the Elkhorn Valley Medical Society at Norfolk, August 24, on "Preoperative Preparation of Exophthalmic Goiter" and "Indications for and Results of Sympathectomy in the Treatment of Thrombo-Angitis Obliterans," respectively. —Dr John F Allen, Omaha, addressed the Otoe County Medical Society, Syracuse, August 28, on recent advances in diagnosis of early tuberculosis. —Drs Donald J Wilson and Ernest L MacQuiddy, Omaha, were the speakers at a meeting of the Madison Six Counties Medical Society at Wisner, September 18, on "Diagnosis and Treatment of Common Skin Diseases" and "Practical Aspects of Allergy," respectively.

NEW HAMPSHIRE

Sanitation of Lumber Camps.—The state board of health recently promulgated regulations designed to improve sanitary conditions in lumber camps. This action was the result of demands for unemployment relief in recent months, according to *Health*, the board's bulletin. The new regulations deal with such matters as proper location of camps, layout of buildings, construction of bunk houses, character and care of bedding to be provided, water supply, garbage and refuse disposal, location and construction of toilets, manure and wastes disposal, protection of public water supplies, sanitation of food handling, examination of food handlers and care of the sick.

NEW JERSEY

Allied Professions Conference.—Representatives of the Medical Society of the State of New Jersey, the New Jersey State Dental Society, the New Jersey Pharmaceutical Association and the New Jersey State Nurses' Association at a meeting, September 12, in the offices of the medical society in Trenton, perfected an organization to be known as the Conference of Allied Medical Professions of the State of New Jersey. The purpose of this society is to provide a medium for discussing matters of common interest to the various groups. It is planned to foster the organization of county and district groups. Meetings are to be held at least once a year and other meetings may be called by the chairman or by action of the conference.

NEW YORK

Society News.—Drs Benjamin I Ashe and Carl H Greene, New York, addressed the Medical Society of Westchester County, October 16, on "Diagnosis and Treatment of Bright's Disease" and "The Modern Viewpoint of Diseases of the Biliary Tract," respectively. —Speakers before the Medical Society of the County of Albany, October 31, included Drs Arthur F Holding and Arthur M Dickinson on "Need for Improved Technic in Tonsillectomy" and "The Schilling Hemo-gram Its Value to the Surgeon," respectively.

New York City

Afternoon Lectures at the Academy.—The annual series of Friday afternoon lectures at the New York Academy of Medicine will begin November 9, with Dr Arthur M Fishberg as the speaker, on "Recognition and Treatment of Peripheral Circulatory Failure (Shock)." The remaining lectures for November and December will be as follows:

- Dr Arthur C DeGraff, November 16, Therapeutic and Toxic Actions of Some Drugs Recently Introduced in the Treatment of Cardiac Disorders
- Dr Edward M Livingston, November 23, Signs and Symptoms in Abdominal Diagnosis
- Dr Robert B Osgood, Boston, December 7, Interpretation of Low Back Pain
- Dr Charles G Kerley, December 14, The Handicapped Child
- Dr Walton Martin, December 21, The Significance of Excision in Treatment of Local Tuberculosis in Bones, Joints and Lymph Glands as Exemplified in the Treatment of Tuberculosis of the Thoracic Wall
- Dr Henry G Bugbee, December 28, Present Status of the Prostatic Problem

Society News.—Drs Soma Weiss, Boston, and William Lintz addressed the Medical Society of the County of Kings, October 16, on "Interpretation and Management of Syndromes Associated with Arterial Hypertension" and "Gastro-Intestinal Allergy," respectively. —Speakers before the Medical Society of the County of New York, October 29, were Drs Arthur F Chace and Eugene H Pool on medical and surgical aspects, respectively, of the diagnosis and treatment of peptic ulcer, and Fordyce B St John, on treatment of carcinoma of the stomach. —Drs Madeline Penke, Corona, and Charles E Farr presented a paper on "Meckel's Diverticulum" before the New York Surgical Society, October 24. —Dr Leonard G Rowntree, Philadelphia, addressed the New York Endocrinological Society, October 24, on "Diagnostic Criteria and Therapeutic Procedures in Diseases of the Adrenal Glands." —Drs Thomas R Brown and Theodore H Morrison, Baltimore, addressed the National Society for the Advancement of Gastro-Enterology, October 24, on "Digestive Symptoms in Diseases Elsewhere" and "Idiopathic Ulcerative Colitis," respectively. —Drs Isaiah A Lehman and Harry Gordon addressed the Bronx Gynecological and Obstetrical Society, October 22, on "Evaluation of Results of Electrosurgical Treatment of Chronic Endocervicitis."

OHIO

Society News.—Dr Harry H McClellan, Dayton, addressed the Hardin County Medical Society, September 20, on "Physical Causes of Mental Diseases." —Drs Charles E Turner, Columbus, and Robert W Lukens, Wheeling, W Va, addressed the Fayette County Medical Society, Washington Court House, September 6, on "Obstetric Hemorrhages" and "Early Diagnosis of Pregnancy," respectively. —Dr William W Weis, Piqua, presented a paper on "The Maggot Treatment of Suppurating Wounds and Osteomyelitis" before the Miami County Medical Society, Troy, September 7. —Dr Roy W Scott, Cleveland, was guest speaker at the first fall meeting of the Marion Academy of Medicine, September 4, on "Problems of Heart Disease from the Practitioners' Standpoint." —Dr Maxwell Harbin, Cleveland, addressed the Stark

County Medical Society, September 11, on management of fractures.—Dr. Carl S. Bickel, Wheeling, W. Va., addressed the Belmont County Medical Society, Bellaire, September 6, on "Toxemias of Pregnancy."—Dr. Robert H. Crawford, Indianapolis, addressed the Toledo Academy of Medicine, October 5, on "Relation of Cell Size to the Classification of Some Commonly Encountered Anemias."—Dr. Norris W. Gillette, Toledo, addressed the Academy of Medicine of Lima and Allen County in Lima, September 18, on "Abdominal Surgery in Children."

PENNSYLVANIA

Record Low Birth Rate.—Health department statisticians have announced a total of 157,059 live births in Pennsylvania during 1933, a rate of 15.8 per thousand of population. Both the actual number and the rate established low records. The birth rate has declined steadily since 1921, when it was 25.9. Last year 96 per cent of all live births were attended by physicians, 3 per cent by midwives, and 1 per cent by persons other than a doctor or midwife.

The Furlough Plan at Sanatoriums.—The state department of health has recently announced a furlough plan for the three state tuberculosis sanatoriums, with a view to decreasing the waiting list, which now numbers more than a thousand. Patients who are successfully receiving artificial pneumothorax treatment are to be returned to their homes and will receive treatment at special clinics. Field nurses and clinicians will watch these patients carefully and return to the sanatorium any who do not show sufficient improvement.

Philadelphia

Meeting on Ophthalmia Neonatorum.—A report on a survey of 27,000 hospital birth records and 2,000 cases of ophthalmia neonatorum made to determine the limitation in the use of silver nitrate was presented by Dr. Louis Lehrfeld at the regular meeting of the Philadelphia County Medical Society, October 24. Dr. Lehrfeld's study was undertaken under the sponsorship of the Philadelphia Committee on the Conservation of Vision, a similar committee of the Medical Society of the State of Pennsylvania, the Philadelphia Department of Public Health and the Philadelphia Health League. It was financed by funds supplied by the Civil Works Administration. Mr. Lewis H. Carris, New York, managing director of the National Society for the Prevention of Blindness, and Drs. J. Norman Henry, George E. de Schweinitz, Barton Cooke Hirst and William R. Nicholson discussed the subject.

RHODE ISLAND

Hospital News.—Drs. William B. Castle and Maurice B. Strauss, Boston, presented papers at a meeting at the Rhode Island State Hospital for Mental Diseases, Howard, October 23, on "Practical Treatment of Anemia" and "Polyneuritis, Spinal Cord Sclerosis and Korsakoff's Syndrome," respectively.

Society News.—Dr. Emanuel A. Henkle, New London, Conn., addressed the Washington County Medical Association, Westerly, October 10, on obstetric problems.—Dr. William Jason Mixer, Boston, addressed the Providence Medical Association, October 1, on "Rupture of Intervertebral Disk as a Clinical Entity."

TENNESSEE

Personal.—Dr. Andrew Richard Bliss Jr., formerly chief of the division of pharmacology of the University of Tennessee College of Medicine, has been appointed professor of pharmacology and to the newly created office of dean of pharmacy at Howard College, Birmingham, Ala., *Science* reports.

Society News.—Drs. Edward A. Oliver, Chicago, and Charles A. Aldrich, Winnetka, Ill., addressed the Gibson County Medical Society, September 24, on diseases of the skin and diseases of children, respectively.—Dr. Tinsley R. Harrison, Nashville, was guest speaker at a meeting of the Madison County Medical Society, Jackson, October 2, on "Treatment of Congestive Heart Failure."—Dr. William D. Haggard, Nashville, addressed the Sullivan-Johnson Counties Medical Society, Kingsport, September 5, on cancer of the colon.—Drs. William W. Wilkerson Jr. and Murray B. Davis, Nashville, discussed eye injuries and abdominal injuries, respectively, as guest speakers before the Robertson County Medical Society, Springfield, in August.—Drs. Edward G. Thompson and John J. Shea addressed the Memphis and Shelby County Medical Society, Memphis, September 4, on "Problems of the Obese" and "Management of Fractures of the Face," respectively.

VIRGINIA

Society News.—Dr. James P. Baker Jr., Richmond, addressed the Southside Virginia Medical Association, September 11, on cardiac asthma. Drs. Dean B. Colc, Frank S. Johns, Richmond, and John A. Proffitt, Burkeville, demonstrated collapse therapy of tuberculosis.—Speakers at a meeting of the Mid-Tidewater Medical Society at Gloucester, July 24, were three Richmond physicians: Drs. Lawrence T. Price, on hematuria; Reuben F. Simms, granuloma inguinale, and Frank S. Johns, surgical gynecology.

State Medical Election.—Dr. Philip S. Moncure, Norfolk, was chosen president-elect of the Medical Society of Virginia at its annual meeting in Alexandria, October 11. Drs. Carrington Williams, Richmond, Samuel B. Moore, Alexandria, and Alexander F. Robertson Jr., Staunton, were elected vice presidents and Miss Agnes V. Edwards, Richmond, was renamed executive secretary. Dr. Francis H. Smith, Abingdon, was installed as president for the coming year. Next year's meeting will be held in Norfolk.

WISCONSIN

Personal.—Dr. George R. Love, Oconomowoc, won the president's cup in the annual golf tournament of the State Medical Society of Wisconsin in Green Bay, in September, with a score of 75.—Dr. Roy T. Hansen has been chosen health officer of Wauwautosa to succeed Dr. Enoch F. Peterson.

Society News.—Drs. Robert S. Baldwin, Marshfield, and Stephen E. Williams, Chippewa Falls, addressed the Clark County Medical Society, September 5, on tuberculous meningitis and anesthesia, respectively.—Dr. Chester M. Kurtz, Madison, presented a paper on "The Physician's Heart" at a meeting of the Dane County Medical Society, Stoughton, September 20.—Speakers before the Tenth District Medical Society at Eau Claire, September 27, were Drs. Alfred A. Strauss, Chicago, on "Surgical Treatment of Gastric and Duodenal Ulcers"; William T. Peyton, Minneapolis, "Diagnosis and Treatment of Malignancy," and William D. Stovall, Madison, "Prophylactic Immunization."—Dr. William P. Murphy, Boston, addressed the University of Wisconsin Medical Society, Madison, September 28, on "The Present Status of Pernicious Anemia."

GENERAL

Society News.—The American Association of School Physicians has established new headquarters at 883 Broadway, Albany, N. Y. Dr. William A. Howe, Albany, secretary of the association, will henceforth devote most of his time to its affairs. Dr. Charles H. Keene, Buffalo, N. Y., is the present president of the association, installed at its recent meeting in Pasadena, Calif.—Dr. John M. Wheeler, New York, was elected president of the Society of Plastic and Reconstructive Surgery at its recent annual meeting in New York; Drs. Warren B. Davis, Philadelphia, and Isadore Goldstein, New York, were elected vice presidents, and Dr. Arthur Palmer, New York, general secretary.—Dr. Robin C. Buerki, Madison, Wis., was named president-elect of the American Hospital Association at its annual session in Philadelphia, and Mr. Robert Jolly, Houston, Texas, was installed as president.

Bequests and Donations.—The following bequests and donations have recently been announced:

Jewish Hospital, Philadelphia, \$5,000 by the will of Dr. Edwin A. Jarecki, former chief resident physician of the hospital.

New York Hospital, New York, \$100,000 by the will of Edward Wright Sheldon, late president of the hospital.

Montefiore and Mount Sinai hospitals, New York Tuberculosis and Health Association and American Red Cross, New York, \$1,000 each by the will of the late Minnie Dessauer.

Hospital for Joint Diseases, New York, \$100,000 by the will of the late Edward W. Browning.

St. Mary's Free Hospital for Children, \$8,000 by the will of Fannie Henrietta Youngs.

Methodist Hospital and James Whitcomb Riley Hospital, Indianapolis, \$100,000 and \$50,000, respectively, by the will of the late Louis H. Levy.

New York Homeopathic Medical College and Flower Hospital, \$50,000 from the estate of the late Dr. John E. L. Davis, made available through the death of Mrs. Davis.

Research on Leprosy.—During the current year the Leonard Wood Memorial for the Eradication of Leprosy has made grants for research in its special field to the following workers:

Dr. Charles M. Carpenter, University of Rochester (N. Y.) School of Medicine, for study of radiothermic treatment of leprosy.

Edmund V. Cowdry, Ph.D., Washington University School of Medicine, St. Louis, for study of histophysiology of lesions of leprosy by micro-incineration.

Dr. Esmond R. Long, University of Pennsylvania School of Medicine, Philadelphia, comparative study of acid-fast bacteria.

Dr. Clarence A. Mills, University of Cincinnati College of Medicine, survey of climate on the incidence of leprosy.

Malcolm H. Soule, LL.D., University of Michigan Medical School, Ann Arbor, Mich., methods of blood culture in tuberculosis and leprosy.

Support of the memorial laboratory completed last year in Culion, P. I., was continued and additional facilities were provided for the Eversley Childs Treatment Station and the Cebu skin clinic built by the Wood memorial and presented to the Philippine Health Service. The memorial fund also supports the *International Journal of Leprosy*.

Hygiene Association Withdraws Sponsorship of Film.—The American Social Hygiene Association announces that it has withdrawn its sponsorship of the commercially produced film "Damaged Lives," which deals with syphilis in family life. Dr. William F. Snow, New York, general director of the association, states that apparently it has been impossible for the owner of the film, the Weldon Pictures Corporation, to control undesirable and unauthorized activities of distributors and exhibitors in the local advertising and showing of the film. The association has notified the firm that the name of the American Social Hygiene Association must be removed from the film and all prints therefrom and from all material used in connection with its showings and has requested the return of the negative and all prints of the lecture film dealing with syphilis, which was shown jointly with the picture. The executive committee believes that the experience, which was undertaken after consultation with health officers, physicians and educators, has been worth while and will possibly pave the way for entirely successful projects in the future. In his letter addressed to members and cooperating agencies, Dr. Snow states that although the films are not being scheduled for future showings, a number of copies have not been turned in and comments from one city indicate that it has been shown there with undesirable and unauthorized modifications of the approved program. He asks that the association be notified if these films are shown or announced in any community.

Southern Medical Association.—The twenty-eighth annual meeting of the Southern Medical Association will be held in San Antonio, Texas, November 13-16, under the presidency of Dr. Hugh Leslie Moore, Dallas. The speakers at the general sessions will be as follows:

- Dr. Robert U. Patterson, Surgeon General, M. C., U. S. Army, Washington, D. C., Military Training of Medical Officers, Regular Reserve and National Guard.
Dr. Frank K. Boland, Atlanta, Interpretation of Abdominal Pain.
Dr. Joseph L. Baer, Chicago, Some Phases of the Conduct of Labor.
Dr. Miley B. Wesson, San Francisco, Urography and the General Practitioner.
Dr. William T. Coughlin, St. Louis, Surgical Relief of Pain About the Head.
Dr. George M. MacKee, New York, Treatment of Skin Diseases by Physical Therapeutic Methods.
Dr. William P. Wherry, Omaha, Chronic Sinusitis from a General Practitioner's Viewpoint.
Dr. Walter L. Bierring, Des Moines, Iowa, President, American Medical Association, Heart Disease and the General Practitioner.
Dr. Francisco de P. Miranda, Mexico City, Physiology of Heart Failure.
Dr. Bernard Myers, London, England, Reminiscences of Interesting Pediatric Clinical Cases.
Dr. Jacques Forestier, Aix-les-Bains, France, Relief of Pains of the Locomotor System by Means of Local Injections of Lipiodol and Their Control by X-Rays.
Dr. H. Kennon Dunham, Cincinnati, Pulmonary Emphysema, an Important Sequela of Chronic Lung Lesions.
Dr. James S. Mc Lester, Birmingham, Ala., President-Elect, American Medical Association, Nutritional Failure as a Clinical Problem.
Dr. Albert H. Rowe, San Francisco, Food Allergy, a Common Problem in Practice.

Discoverers of Liver Treatment Share Nobel Prize.—Drs. George R. Minot and William P. Murphy of Harvard Medical School, Boston, and George H. Whipple of the University of Rochester, Rochester, N. Y., have been named winners of the Nobel Prize in medicine for 1934. The prize, which this year totals \$41,000, was awarded to the three physicians "for liver therapy in anemia." Dr. Minot, who is 49 years of age, graduated from Harvard in 1912. During his career he has been associated with Johns Hopkins University School of Medicine and various institutions affiliated with Harvard, where, since 1928, he has been professor of medicine. In 1928 he was awarded the Kober gold medal of the Association of American Physicians and the Charles Mickie fellowship of the University of Toronto; in 1930, the Cameron prize of the University of Edinburgh and the gold medal of the National Institute of Social Sciences; and in 1931 shared with Dr. Whipple the gold medal and \$10,000 award of *Popular Science Monthly*. Dr. Whipple graduated in medicine at Johns Hopkins University in 1905. He is 56 years of age. In 1914 he left Johns Hopkins, where he had been a member of the faculty since 1909, to become professor of research medicine at the University of California and director of the Hooper Foundation for Medical Research, San Francisco. He was dean of the medical school from 1920 to 1921, when he was appointed dean and professor of pathology of the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., his present position. Dr. Murphy is 42 years of age

and an alumnus of Harvard, where he is now instructor in medicine. In 1930 he shared the Cameron Prize with Dr. Minot.

Rockefeller Foundation Aids Research in Mental Health.—The major emphasis of the activities of the Rockefeller Foundation in 1933 in the field of medical science was placed on the problem of mental health. Of a total of \$9,890,806.31 expended by the foundation for philanthropic projects, \$1,173,853 was appropriated for the advancement of medical science. Programs concentrating specifically on psychiatry and public health teaching were aided at Johns Hopkins University School of Medicine for research in psychiatry; University College, London, for work in biophysics and neurophysiology; Washington University, St. Louis, for investigations in nerve physiology, and Harvard Medical School and Massachusetts General Hospital for cooperative work in psychiatry. In addition Dalhousie University, Halifax, N. S., received an appropriation for development of teaching in public health. During 1933 the foundation provided 295 fellowships in the medical sciences and by research grants enabled sixty-one scientists or groups of scientists to carry on research. For public health work during the year the foundation expended \$3,286,063.01. Projects for the control of yellow fever were supported in Africa, Brazil, Bolivia and New York; malaria control in three states of the United States and seventeen foreign countries; studies of hookworm disease in Palestine, Egypt, Straits Settlements and Puerto Rico; studies of Endamoeba histolytica, Rocky Mountain spotted fever, tuberculosis, sprue anemia, filariasis, schistosomiasis, and the diseases affecting the races of the Pacific. Among other activities the foundation also aided the government of India in conducting experiments on the disposal of refuse; sponsored studies of statistical epidemiology; contributed to development of health service in many foreign countries, as well as in various areas in the United States; contributed to the support of schools of hygiene and public health and centers of training in Japan, Puerto Rico, Central America, South America, Europe and the United States. Appropriations in the field of the natural sciences included funds to the National Research Council for research in problems of sex and the effects of radiation on living organisms and to the Roscoe B. Jackson Memorial Laboratory in Bar Harbor, Maine, for research in mammalian genetics. The remainder of the year's appropriations were placed in the fields of social sciences and the humanities and in emergency grants, the last including funds contributed to both American and European universities for salaries of scholars displaced from their positions in foreign schools for political reasons.

Government Services

Medical Director Appointed for FERA

Dr. Clifford E. Waller, assistant surgeon general in charge of the states relations division of the U. S. Public Health Service, has been appointed medical director for the Federal Emergency Relief Administration. Dr. Waller will direct the policies and activities of the administration in the field of medical relief for the unemployed and advise the various divisions on health and sanitation matters. He will also advise in the development of work-relief activities that promote health, such as the malaria control projects and nursing work. He will continue to devote part of his time to his work with the public health service.

Changes in Public Health Service

Passed Asst. Surg. Fred W. Kratz, relieved at Angel Island, Calif., and assigned at Portland, Ore., in charge of service activities at that place.

Medical Director Emil Krulish, relieved at Portland and assigned at Los Angeles, in charge of the relief station.

Asst. Surg. Ralph J. Mitchell, relieved at New Orleans Marine Hospital and assigned at Marine Hospital, San Francisco.

Passed Asst. Surg. Frank S. Fellows, relieved at Albuquerque, N. M., and assigned at the Marine Hospital, New Orleans.

Sr. Surg. Robert H. Heterick, relieved at Los Angeles and assigned at Albuquerque, N. M., for duty in connection with the supervision of administrative affairs in connection with the control of communicable diseases among the Indians.

Surg. William Y. Hollingsworth, relieved at Marine Hospital, New Orleans, and assigned at Louisville in charge of the Marine Hospital.

Surg. Frank V. Meriwether, relieved at Ellis Island, N. Y., and assigned at Oslo, Norway, for duty in the office of the American Consul for the examination of aliens.

Passed Asst. Surg. Ralph Gregg, relieved at Dublin, I. F. S., and assigned at Ellis Island, N. Y.

Asst. Surg. Alexander G. Gilliam, relieved at Los Angeles and assigned at the Marine Hospital, Seattle, Wash.

Surg. Walter G. Nelson, relieved at Oslo, Norway, and assigned at Dublin, for duty in the office of the American consul general, in connection with the examination of aliens.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 5, 1934.

The Health of the Nation

In the annual report for 1933 of the Chief Medical Officer of the Ministry of Health (Sir George Newman), the estimated population in England and Wales in the middle of the year is stated to have been 40,350,000.

THE DECLINING BIRTH AND DEATH RATES

The two great features of English vital statistics during the past half century are the considerable declines in the birth and death rates. In the decade 1871-1880 the annual birth rate averaged 35.4 per thousand persons living. A continuous fall then set in. In the decade 1921-1930 the rate was almost halved, being only 18.3. Moreover, the individual years throughout this decade, as well as those which have followed, have shown a rapid and almost continuous fall. In 1926 the birth rate was 17.8; in 1927, 16.6; in 1928, 16.7; in 1929, 16.3; in 1930, 16.3; in 1931, 15.8; in 1932, 15.3, and in 1933 (the year now under review) 14.4. The fall of the birth rate is such that statisticians have calculated that in 1940 the population will cease to increase and after that will decline.

As to the death rate, this averaged 21.4 in the decade 1871-1880. The great advances in hygiene have so reduced it that in the decade 1921-1930 it was only 12.1. In 1933 it was 12.3. The five principal causes of death gave the following figures per thousand deaths for 1933: diseases of the heart and circulatory system, 269; cancer, 124; respiratory diseases, 113; diseases of the nervous system, 79; tuberculosis, 67. The infant mortality has also shown a great decline. In the quinquennium 1871-1875 the deaths of infants under 1 year averaged 153 per thousand live births; in 1930 the figure was only 60, the lowest on record; in 1933 it was 64.

INFECTIOUS DISEASES

The decline in the mortality of the infectious diseases in the last thirty years is remarkable. The typhoid death rate fell from 174 per million persons in 1900 to 6 in 1932. For ages under 19 years the measles death rate, calculated in the same way, showed a fall from 1,199 to 455; the scarlet fever, from 340 to 46; the diphtheria, from 936 to 229, and the whooping cough from 1,090 to 310. But incidence has not always kept pace with mortality. The annual number of cases of diphtheria has been practically constant for twenty years.

TUBERCULOSIS

In 1933 there were 33,259 deaths from tuberculosis, against 33,658 in 1932. In the decade 1871-1880 the average annual death rate from tuberculosis per thousand of population was 2.88; in that of 1881-1890, 2.43; 1891-1900, 2.02; 1901-1910, 1.66; 1911-1920, 1.43, and 1921-1930, 1.01. In curious contrast to this general fall, however, a rise in the death rate of single young women (aged from 15 to 25 years) became apparent in 1917 and the subsequent years and was most marked in London. The report states that the causes of this increase have never been definitely ascertained. The increase in the number of women employed in industry, with the fatigue consequent on the nature of the employment and the journeys to and from home in overcrowded trains, buses and trams, want of rest and late going to bed after dancing and other amusements have been suggested as causes; also unsatisfactory meals, such as the "tea and bun" lunch.

VENEREAL DISEASES

The official scheme for the treatment of venereal diseases has been in operation for eighteen years. Its principles are

the education of the public in the danger of these diseases and the provision of centers for their treatment. In the treatment of syphilis considerable success has been attained. The greater number of persons infected resort to the centers. The new cases treated there amounted to 42,805 in 1920. In 1924 they fell to 22,010 and in 1933 to 21,525, the lowest number on record. Syphilis is not now transmitted to wives and offspring to the same extent as in the past.

CANCER

The deaths per million of population from cancer were 1,526 in 1933, an increase of 16 over 1932. The increase of cancer is shown by the following figures: In the quinquennium 1901-1905 the crude death rate from cancer per million was 867; in 1926-1930, 1,411. The increase in the crude death rate is attributed to the average lengthening of life of the population. Sir George Newman considers that there is a changing outlook in cancer prevention. When cancer became a subject of experimental research it was thought that some method of causation would be discovered which would indicate a road to prevention. It is now thought that the changes in the cells which have undergone malignant transformation are no more than pathologic, perhaps even physiologic, reactions to one or more of a wide variety of stimuli, more or less peculiar to the different organs affected. The need is for minute investigation of the abnormal conditions which determine the emergence of cancer, conditions which probably differ widely for different organs. There is a feeling of growing dissatisfaction with the results of laboratory research, and it is suggested that in the future attention will be turned to clinical research.

Nutrition and the Industrial Depression

The evidence collected indicates that the general health of the population is well maintained in spite of economic difficulties. The health of the unemployed and their dependents, as a whole, is not suffering seriously or generally, though of course there are exceptions. Many of the unemployed in the distressed area show the inevitable physical signs of prolonged deprivation, though not deprivation comparable in degree with that of certain periods in the nineteenth century. There is no question that the nutrition of the English people today is better than that at any period of which there are records. So far as the death rate is any criterion, of the six English and Welsh counties most seriously affected by the industrial depression, two had a general death rate actually below the average for the country and in the others it was only slightly higher. But the infant death rate in nearly all these areas was above the national average.

Aerial Medical Service in Australia

In the sparsely settled parts of Central and Northern Australia, the aerial medical service of the Australian Inland Mission has proved a great boon. Recently a woman in a cattle station hundreds of miles from the nearest township was taken suddenly ill. Within thirty-six hours she had been taken 700 miles to a hospital at Camooweal. This feat was accomplished by the aid of wireless and airplane. When it became apparent that the illness was serious a girl motored 70 miles to another cattle station, which is equipped with one of the mission's pedal-transmitter wireless sets. These sets are an Australian invention and are so simple that no training is required to use them. A message describing the woman's illness was tapped out on a device like a typewriter, operated by pedals like those of a bicycle. As the operator spelled out each word it was converted into Morse by the machine and automatically transmitted by wireless telegraphy. The message was picked up at the mission's chief country center at Cloncurry, North Queensland. A few minutes later listeners at the cattle station heard the voice of the "flying doctor," Dr. J. M. Rossell, asking for more information about the woman.

This was again spelled out on the pedal-transmitter. An airplane with a pilot and the doctor on board left Cloncurry for the station where the woman was ill. On arriving the doctor attended to the patient, placed her on a stretcher in a special compartment of the airplane and flew with her to the hospital at Camooweal, where the operation was performed. The Australian Inland Mission has twenty wireless sets of the pedal-transmitter type at key positions in Northern Australia. This particular airplane has flown more than 100,000 miles for the mission without a serious accident, a remarkable performance considering that it mostly has to land on rough station paddocks.

Suppression of a Burdensome Tax on Physicians

The French medical profession has just been given an important reduction in taxes. According to a law dating back to 1880, a physician was obliged to pay a relatively high percentage on his net income (after deduction of expenses incurred in the exercise of his profession).

There were two other taxes, one similar to the personal property tax in the United States, which amounted to about 25 per cent of the rental of his domicile, and a second more obnoxious form of taxation, termed the "patente," or privilege to practice, also based on the rental value of his domicile, which was equally burdensome, amounting to about 40 per cent of the rent paid. If a physician had an office in another building than that in which he resided, he was obliged to pay the "patente" a second time, and even a third time if he had a country home. The result has been that medical practitioners have been greatly handicapped, being obliged to adapt themselves to inadequate facilities in their domiciles.

These various taxes have left physicians but little of their hard-earned income and have been a discouragement to young men about to engage in practice. Fortunately, one of these taxes, the "patente," which does not exist in the United States, has just been suppressed, so that the burden has been considerably lightened.

In spite of their reputation for honesty and neglectful of the immense amount of services rendered gratuitously, the taxing powers do not trust French physicians. In order to keep a check on medical incomes, every practitioner is now obliged to keep a book giving the name of every patient treated, and the amount received from each one. In order to maintain professional secrecy, a patient can be given a number instead of being listed by name.

Rôle of the Filtrable Virus in Infantile Tuberculosis

At the French Pediatric Congress in July, Paiseau and Valtis read a paper on the rôle of the filtrable virus in infantile tuberculosis. The presence of a filtrable tuberculosis virus in the organs of both healthy children at birth and in guinea-pigs whose mothers were tuberculous is well established by the work of Calmette and others. The authors have obtained similar results by the inoculation of guinea-pigs with nonfiltered tuberculous material obtained from human beings. This raises the questions not only of whether heredity plays a part in tuberculosis, but also that of the part played by the filtrable virus in the pathogenesis of human tuberculosis.

The authors emphasize the necessity of protecting the healthy infant from being infected by a tuberculous mother or other member of the family, despite the apparent handicap which these investigations imply as to heredity and antepartum infection. Infection from those who are suffering from tuberculous lesions in close contact with children must still remain the most common source.

The studies made by these authors reveal the existence of a difference between reactions to tuberculin and to the filtrable ultravirus, which can perhaps be utilized to distinguish certain types of "inflammatory tuberculosis" in which the filtrable virus plays an important part.

One can isolate in cases of polyarticular rheumatism, nephritis, purpuras and other diseases, both in adults and in children, acid-fast bacilli that present most of the characteristics of the elements obtained from the filtrable virus. This permits one to make the deduction that in these diseases there is a pathogenic action by the filtrable elements of the tubercle bacillus.

The missing link in the chain of evidence of the relation between so-called inflammatory tuberculous diseases and tuberculosis as it has been accepted up to the present time is that in the former group one does not find the lesions which, since Poncet, have been regarded as typical of infection by the tubercle bacillus. Views on the results of guinea-pig inoculation with tuberculous products from the human being must be modified. In the future, the absence of typical tuberculous lesions in the inoculated guinea-pig does not imply the non-existence of tubercle bacilli in the secretion, excretion or tissue from which the inoculated material was taken.

Ribadeau-Dumas, in the discussion of this paper, stated that a maternal tuberculosis did not seem to have much influence on healthy new-born infants, and the impregnation of the human organism by the filtrable tuberculosis virus could not be regarded as much of a menace.

Paiseau, in closing, drew attention to the fact that there still exist many anomalous factors in the question of research on the subject of tuberculosis. There may be some other still unsolved question than that of the filtrable ultravirus. If the bacillus and the tubercle are not constantly associated, one fails to see why the virulence of the bacillus should be the sole invariable factor.

Commemoration of the Services of the American Ambulance of Neuilly During the World War

In the presence of American and French officials, a tablet has just been placed in the Neuilly high school building, which was used as a hospital by the first ambulance corps to be placed in service during the World War. Less than a month after the declaration of war, the organization was ready to convey the wounded to Paris. About 250 physicians and surgeons and 650 civilians of both sexes devoted their energies to the care of the wounded in this hospital. From Sept. 1, 1914, to July 1917, more than 12,000 French soldiers were cared for. After the United States entered the war, a large number of American soldiers were cared for in the building and it became a part of the army medical service.

Coexistence of Hyperthyroidism and Hyperpituitarism

At the July 10 meeting of the Academy of Medicine, Drs. Etienne and Drouet said that the reason failures occur in the treatment of hyperthyroidism is the inability to appreciate the fact that there is an alteration in the function of the hypophysis as an associated lesion. The fact that the basal metabolic rate is lowered by simple irradiation of the hypophysis proves that the hyperactivity of this gland dominates hyperthyroidism. Under these conditions, one ought not to limit the treatment of hyperthyroidism to radiotherapy, administration of iodine or thyroidectomy. It is essential to treat the excessive activity of the hypophysis at the same time by radiotherapy of this structure.

Radiotherapy of Furuncles of Upper Lip

Dr. Faure and his associates report excellent results following the use of radiotherapy in this grave localization of pyogenic organisms. Surgeons feel that operative measures are often of no avail in preventing intracranial complications of furuncles

of the upper lip and hence the authors feel that their success in six cases merits the application of radiotherapy. The rapid improvement (after a few days) was striking. They cite the statistics of Baensch, who treated 109 furuncles of the face (twenty-one of the upper lip and twenty-four of the nose) with a mortality of only 1.9 per cent following the use of radiotherapy alone. In the fatal cases there were already symptoms of thrombosis of the cavernous sinus at the time treatment was begun. In 103 cases treated surgically at an adjacent clinic there was a mortality of 10.3 per cent.

Renal Intolerance of the Type of Lipoid Nephrosis Following Treatment for Syphilis

At a recent meeting, Dr. Tzank and his associates reported two cases of lipoid nephrosis following the administration of small doses of antisyphilitic drugs. The same observations have been reported after the use of gold salts in pulmonary tuberculosis and after scrotherapy. The authors believe that there is a type of renal intolerance which presents clinically the symptoms of a lipoid nephrosis. This corroborates the opinion held in France as to this form of nephrosis; viz., that it is a clinical syndrome the etiology and character of which depend on a number of different pathologic lesions.

Death of Prof. Léon Bernard

One of the leaders in the international fight against tuberculosis has just died of cerebral hemorrhage. He was one of the first to create a special service in public hospitals for the treatment of pulmonary tuberculosis. This new ward service and the outpatient department were under his constant supervision. They served as models for the remarkable organization that now exists in all parts of France and its colonies, in the form of services in city hospitals, dispensaries and sanatoriums, all well coordinated to combat a disease that is prevalent in France. Léon Bernard also played an important part in the organization of the International Congress on Tuberculosis and was for a time its secretary general.

The Causes of the Heavy Mortality of Male Fetuses

Professor von Pfaundler, pediatrician, of Munich, delivered an address recently on "The Causes and the Significance of the Heavy Mortality of Male Fetuses." By "early death" is meant deaths that occur before the end of the first year of life, including also the prenatal deaths. The so-called stillbirths occur between the eighth and the tenth month of pregnancy (about 30,000 in Germany), while the miscarriages occur during the first seven months of pregnancy. Reliable statistics are not available, particularly in regard to the miscarriages of the first few months. One can, however, make an estimate. From statistics that included no wilful abortions, Pfaundler estimated that there are 280 miscarriages for each thousand births. Of 2,010,000 conceptions annually, 910,000 reach the first year of life. Fetal deaths are, therefore, much more frequent than is supposed. Since greater importance attaches to the quality of offspring than to the quantity, the question arises what values are lost. Is this high mortality a weeding-out process of nature? In comparisons with animals, it has been found that in pigs there are 28 abortions to 100 conceptions; in rats, 33 abortions, and in man, 22 abortions. Of the human procreations, 45 per cent die before they reach the procreative stage. In all animals and plants the proportions are less favorable. In illustration, it was stated that the female sturgeon deposits several million eggs, all of which are impregnated. If only one million survived and matured and reproduced, in the third generation the sturgeon spawn would be

unable to find sufficient room on earth, and in the fourth generation sturgeon spawn would exceed in mass the earth itself; hence the early death of multitudes is here an absolute necessity.

The pathologist can shed light on the cause of fetal deaths. According to these observations, eighty out of a hundred pregnancies end with birth; of the remaining twenty, seven are abortions; one is a monster; the twelve fully developed fetuses are not always normal; in fact, most of them show abnormalities that may be regarded as the consequences of actual malformations. Malformations are regarded as of hereditary origin. Among the miscarriages there are more males than females, the percentage of males becoming relatively greater the nearer the deaths lie, in point of time, to the conception period. By applying extrapolation methods it may be computed that 146 males are conceived as against 100 female individuals. The mortality among the females is slight, being about the same as in infants. With the males it is different; for, by the end of the first month after conception, 200 out of a thousand have perished. The higher death rate of one sex is well known, a genotypic illustration being the fact that only men die from the effects of hemophilia. In the opinion of Lenz, the deaths among the male embryos are conditioned by recessive, sex-bound lethal factors. These causes can cause damage only in the genotype, this being associated with the composition of the twenty-fourth chromosome; that is to say, lethal factors and hereditary units, which, with external manifestations not understood in detail, lead to an early death of the individual. According to this conception, the higher mortality among the male embryos would effect a wholesale elimination of recessive lethal factors. These views appear to harmonize with the known figures.

The deaths occurring at term or thereabouts are associated, for the most part, with injuries in the mother, so that probably here also selective processes are at work. It is highly probable that the defects of the mother find expression in the genotype of the child. Likewise during the birth period the percentage of male deaths is relatively higher. Aside from the fact that the head of males is larger than that of females, Pfaundler thinks that also a sublethal factor is involved, since the excess mortality observed in males holds good still in the group delivered by cesarean section. The male sex is, in point of fact, the weaker, with its forty-seven nuclear fibers as against forty-eight in females. More boys die from all possible diseases, including constitutional diseases, as is revealed by the statistics of the German reich. Pertussis alone constitutes an exception, for the incidence and the mortality of this disease are higher among females. The reasons for this fact are not understood.

Influence of the Weather on Eye Diseases

It has been shown by Professor de Rudder that disturbing layers of the atmosphere that appear at the junction of two bodies of air play a part in the origin of so-called weather diseases. The presence of such a layer can be ascertained by the weather bureaus by observations on the barometer, the temperature, cloud formation and the amount of precipitation. Of the eye disorders caused by the weather, acute attacks of glaucoma are well known. Dr. Rohrschneider of Greifswald points out that research has shown that many cases of herpes corneae present all the characteristics of a weather disease. The weather is the nonspecific cause of the disease manifestation, its effects being brought about by modification of the reactivity of the vegetative nervous system; in addition there is of course also a specific cause.

Distinct from the weather diseases are the "seasonal diseases." The precipitating factor in the seasonal diseases has not yet been ascertained. For example, *ulcus serpens* in Greifswald (Pomerania) shows a peak at harvest time, in July and August.

An example of a genuine seasonal disease, with a summer peak, is conjunctivitis induced by diplobacilli, with its peak in June and July. The scrofulous diseases of the eye give evidence of a regular increased incidence in spring, with the peak falling in March.

Dr. Ortman, of the Pathologic Institute of the University of Berlin, recently endeavored to discover whether the weather plays a part in the causation of death. It was not possible to demonstrate a distinct dependence of the mortality figures on atmospheric pressure, temperature, vapor tension, humidity, direction and velocity of the wind, cloud formations and precipitations, but he was able to demonstrate the influence of disturbing strata of the atmosphere. Peaks in the mortality coincided with so-called front days; that is, with days on which a cold wave or a warm wave passed over Berlin. A differentiation proved possible also between the various types of disease, between summer and winter, and between the actions of various changes in the weather.

Foreigners Subject to the Sterilization Law

A decision of the Berlin eugenics court has been approved in a comment by the referee of the minister of justice to whom the matter was submitted. The comment confirms that the court rightfully assumes that foreigners also are subject to the law for the prevention of hereditary defects in posterity. The correctness of his view is evident from the general principle that foreigners, during the period of their stay in Germany, are subject to the German laws. The eugenics court is likewise correct in calling attention to the fact that the foreigner can justly claim the right to leave the territory of the reich and thus escape the execution of the order. The purpose of the federal law is to remove from the German people the menace of hereditary diseases. That purpose is attained if the foreigner with hereditary and transmissible defects shall leave the territory of the reich.

MADRID

(From Our Regular Correspondent)

Sept. 5, 1934.

Health Conditions in Spain

Dr. Palanca, formerly director of public health and hygiene, recently published some important data on health conditions in Spain. In dealing with the problem of sewage in Madrid, he said that the sewers empty into the Manzanares River without any previous treatment. The sewage waters in Madrid increased from 12,500,000 liters daily in 1877 to 250,000 cubic meters at the present time, which is more than 4 cubic meters a second. The Manzanares River has a flow of about 700 liters a second, which is a small quantity of water for the dilution of the sewage from Madrid. Water from the Manzanares River is used to water vegetable gardens in Madrid, and these gardens seem to be responsible for epidemics of typhoid. Some time ago Drs. Palanca, La Rosa and Vallejo studied the bacteriologic changes of the waters of the Manzanares River in its course. They found that as soon as the sewage waters from Madrid empty into it their bacteriologic conditions improve a great deal, and it is only 60 kilometers from Madrid, at Aranjuez, that the waters of the Manzanares, having now emptied into the Jarama River (an affluent of the Tagus River) become normal. Dr. Palanca stated that, although it is claimed that sewage waters improve the conditions of horticulture, their use is unhygienic. He reviewed the causes of the higher incidence of infections in the cities than in rural communities. The statistics of 1932 and 1933 gave an average mortality of 16.44 per thousand inhabitants for the nation in a whole. All the Spanish cities except Madrid, Barcelona, Palma de Mallorca, Valencia, Santa Cruz de Tenerife, San Sebastián and four others gave an average mortality higher than that. Palencia

gave the highest average mortality (29.93 per thousand inhabitants). No provincial capital gave a lower mortality rate than that of its province in a whole. The mortality due to infections was 4.69 per thousand in provincial capitals and 3.94 for the nation as a whole. The birth rate diminished from 28.34 per thousand in 1932 to 27.81 in 1933. Almeria and Barcelona were the provinces with the highest birth rate (38.18 and 16.39 per thousand, respectively). The mortality from heart diseases and typhoid was higher in 1933 than in 1932, while that from measles and diphtheria diminished. The mortality from homicide increased from 1.02 per thousand in 1932 to 1.36 in 1933; that is, more than 50 per cent.

The Value of Cholecystography

In a lecture before the Academia Medicoquirurgica Española on the value of cholecystography and of duodenal catheterization in the study of evacuation of the gallbladder, Dr. Larrú, a radiologist, described his investigations on the cholecystokinetic power of butter when it is added to several food substances. Boyden's meal consists of four egg yolks added to 280 Gm. of cream. The ingestion of egg yolks alone is efficacious in evacuation of the gallbladder. The speaker made investigations on the cholecystokinetic action of several drugs: thyroxine, acetylcholine, parathyroid extract, solution of pituitary (by the intravenous or the subcutaneous route) estrogenic substance and magnesium sulphate (through a duodenal sound). The results of the administration of these drugs are inconstant, and their cholecystokinetic action is far behind that of egg yolk. The duodenal injection, through a catheter, of either a 25 or 30 per cent solution of magnesium sulphate, or of a 5 or 10 per cent solution of Witte's peptone in water, according to Stepp's method, or of a mixture of the two substances, failed to evacuate the gallbladder; yet the roentgen shadow of the gallbladder rapidly disappeared following the injection of egg yolks through the duodenal sound. A diagnosis of the functional condition of the gallbladder cannot be based on the results of duodenal catheterization, since the duodenal catheter reaches a duodenal crossway where there are secretions from the gallbladder, the bile ducts, the duodenum, the pancreas and the stomach, which make a diagnostic interpretation difficult. Except when indicated, it is advisable to avoid repeated duodenal catheterization of certain patients, because it has a harmful effect on the hepatic cells. As a treatment for retarded evacuation of the gallbladder, which frequently complicates infections, as typhoid, it is advisable to give the patient some egg yolk. This treatment is not indicated if there is calculous cholecystitis.

Dr. Vital Aza spoke on the dangers of the intravenous injection of solution of pituitary used as a cholecystokinetic agent. In regard to the cholecystokinetic action of egg yolk he said that Napolcon, who suffered from a gastrohepatic disease, frequently resorted to the ingestion of two egg yolks in some milk, which was followed by an abundant bowel evacuation with a great quantity of bile in the feces.

Dr. Oliver said that the data given by the duodenal catheterization on the functions of the gallbladder are more exact than those given by cholecystography. The gallbladder, which from the clinical point of view and from the results of the duodenal catheterization can be considered as atonic, cannot be so considered sometimes by the results of cholecystography. The problem of atony of the gallbladder bears a certain relation to the physiology of the duodenum, and the treatment of atony of the gallbladder is the same as that of duodenitis. In the treatment of duodenitis, Dr. Oliver uses vaccines prepared from cultures of duodenal secretions given through a duodenal sound.

Clinical Value of Continuous Proctoelysis

Dr. Vital Aza, before the members of the Academia Medicoquirurgica de Madrid, discussed the clinical value of continuous

proctoclysis. According to the teachings in Forgue Massaban's Gynecology (1916), continuous proctoclysis permits the rectal absorption of enormous quantities of liquid (from 8 to 12 liters in twenty-four hours). It is said that under its influence the vascular tension rises, the diuresis increases, thirst attenuates and peristalsis is reestablished. Fifty drops of fluid is injected in a minute, which makes 180 cc. an hour and 4,320 cc. a day. Since the injections are given with intervals of rest (one hour of administration and an hour of intestinal rest), this reduces the amount of fluid to be injected to 2 liters a day. There are other factors, such as variations in the technique, the uneven intestinal absorption in different cases, the care of the patient by nurses, the intestinal reflux of more or less quantities of the fluid and the expulsion of the fluid after a temporary storage in the intestine, which bring the quantity absorbed to about 300 or 400 cc. a day. Continuous proctoclysis is of value to promote the reestablishment of the intestinal peristalsis, which is necessary for the treatment of postoperative intestinal paresis, but not for the absorption of large quantities of fluid by the organism.

Dr. Gutierrez Arrese stated that dextrose solution provokes congestion of the intestinal mucosa. The absorptive capacity of the rectum is scanty, especially beyond the ascending and transverse segments of the colon. In order to restore hydration of a patient it is advisable to resort to the hypodermic route of administration. In many cases continuous proctoclysis provokes a local irritation and catarrhal rectitis, frequently of an intense form, owing to the presence of the sound in the rectum.

Canine Leishmaniosis in Madrid and Infantile Kala-Azar

Dr. Rivera Bandres recently did some research on the presence of canine leishmaniosis in Madrid and its relation to endemic infantile kala-azar. As material for his studies he used dogs from the municipal department of unclaimed dogs. From February 1933 up to the present he has performed necropsies on 450 dogs. Special studies were made with the spleen, the liver and the bone marrow. Leishmaniosis was discovered in twenty-nine dogs, or 6.4 per cent. The lesions were cutaneous and mucocutaneous in 24 per cent of the cases. Their anatomicopathologic characteristics were of a chronic type. The areas having a higher incidence of infantile kala-azar in Madrid coincide with those infested with canine leishmaniosis. Dogs with leishmaniosis frequently showed the presence of ocular lesions (purulent conjunctivitis and specific keratitis). The parasites of human and canine leishmaniosis are probably identical, although adapted in the latter case to the conditions of the host. Cutaneous lesions perhaps constitute the port of entry and the primary localization of the parasite. The presence of leishmaniosis in dogs without any manifestations suggests the possible existence of latent human carriers. The investigator stated that dogs can be considered as reservoirs of the virus of leishmaniosis. Dogs with cutaneous and mucocutaneous leishmaniosis may spread the disease through insects, especially fleas and *Phlebotomus*.

Defenders of the Medical Profession in Madrid

The medical profession in Spain, especially in Madrid, can be divided into two groups: The first consists of a few physicians who have political influence, with many positions and a profitable practice; the second group, the majority, comprises those physicians whose income from the profession hardly provides the necessities of life. The three principal causes of the critical economic conditions of the Spanish medical profession at present are (1) the admission of patients to free consultation, (2) the uneven distribution of positions controlled by the few, and (3) the health insurance societies. Four fifths of the population in Madrid belong to these insurance societies.

A group of young physicians recently formed *La Liga de Defensa Médica*, to defend the rights of the medical profession in Madrid. The members of the league have put in effect, since last December, the regulations given by the *Colegio de Médicos de Madrid* (an association of physicians), according to which free medical care should be given only in emergency cases and when the poverty of the patients has been proved. The centers of free medical consultation have been notified of the regulations, which will be maintained by force, if necessary. They also hope to find, in the near future, a solution for the problems of monopolization of positions by a few physicians and of those that arise from the insurance societies for medical care.

Internal Secretions of Sex Glands and Gout

Dr. Marañón recently reported to the *Academia Nacional de Medicina* of Madrid his experimental observations on the relation between internal secretions of the sex glands and gout. Gout is frequent in ovarian insufficiency and in the early menopause. In man it is frequent after sexual excesses. The speaker believes that the female sex hormone is antagonistic to gout while the male sex hormone favors it. By injecting 500 units of estrogenic substance in a group of women and by keeping them on a uniform diet for a week, he was able to observe in twelve of the women the mobilization of blood uric acid and its appearance in the urine. The results were less manifest with injections of corpus luteum extract. The male hormone does not seem to exercise any mobilizing effect on blood uric acid.

The Adulteration of Food in Madrid

The prices for food in Spain are high. In spite of this fact, food, especially milk, is frequently adulterated. The technicians in the municipal department for the control of the quality of milk sold in Madrid find that more than half of the samples examined have been adulterated, by the addition of the milk of other animals (sheep or goats) or of other substances. The sale of sheep's milk is prohibited in Madrid. Nevertheless more than 100,000 liters of it is sold daily in the city. Municipal regulations require that the public be informed when the milk on sale is from goats, but this milk is sold without notification of its nature. The bacterial contents of milk for the general daily supply should not exceed 30,000 bacteria per cubic centimeter in Italy and the United States and 50,000 per cubic centimeter in England. In Spain it contains about 1,000,000 bacteria per cubic centimeter.

Synthetic products have largely been substituted also for the natural juices of fruits. Dyes are used to falsify the natural color of cold meats and the color of egg yolks in pastry. Wines and chocolate are also adulterated. Of 17,397 samples of food examined during the last year at the municipal laboratory of Madrid, 50 per cent of the samples had been adulterated.

Dining Room for Indigent Patients with Diabetes

Dr. Carrasco Cadenas, a specialist in nutritional diseases, opened a free dining room for indigent diabetic patients in Madrid. The injection of insulin is given, also free, to patients who need it. The wife of Mr. Alexander Lerroux, the president of the cabinet of ministers, devotes a great deal of time to this work. Some persons have criticized the institution, saying that the money thus spent ought to be spent in the fight against tuberculosis.

Dr. Huertas

Dr. Francisco Huertas, aged 86, professor of clinical medicine at the General Hospital of Madrid for sixty years, is dead. He represented the Spanish medical profession at several international congresses of medicine. He was a member of the *Academia Nacional de Medicina* of Madrid and author of several books on internal medicine.

Marriages

PAUL E. WYLIE, Hohenwald, Tenn., to Miss Virginia Fischer of Hazen, Ark., in Scotts Hill, Tenn., September 15.

JAMES F. REILLY, Vincennes, Ind., to Miss Amy Louise Spencer of Logansport, in Terre Haute, October 13.

VIRGIL MORRISON, Atchison, Kan., to Mrs. Louise Sheeks of Kansas City, Mo., at Liberty, Mo., September 4.

AUGUST H. WITTENBORG to Miss Margaret Kroesche, both of Memphis, Tenn., in New York, September 15.

STUART H. PERRIN, Superior, Wis., to Miss Esther Catherine Cleary of Prior Lake, Minn., September 29.

WILLIAM BRUCE SCHAEFER, Toccoa, Ga., to Miss Orville Tyler of Barnesville at Griffin, October 6.

GEORGE BUTTERFIELD SALTER, Norfolk, Neb., to Miss Audrey Bauer of Erie, Pa., in August.

MORRIS HARRIS, Morristown, N. J., to Miss Rachel Spitz of Poughkeepsie, N. Y., September 4.

JOHN J. D'URSO, Lawrence, Mass., to Miss Vera M. Shannon of Philadelphia, July 14.

THEODORE W. FALKE, Dayton, Ohio, to Miss Betty Celeste McKirch of Chicago, October 20.

VERONICA C. BARRETT, Brooklyn, to Mr. William F. Fagan of Pascoag, R. I., September 22.

CRAWFORD FANNIN BARNETT JR. to Miss Penelope Brown, both of Atlanta, Ga., October 9.

CHARLES SHERBURNE SENTELL to Miss Sallie Hutton, both of Minden, La., October 2.

CARL J. WOLF, Fremont, Ohio, to Miss Marian Ickes at Cincinnati, September 24.

KENNETH K. KRANING to Miss Virginia Speicher, both of Indianapolis, August 29.

EARL CONOVER to Miss Mildred Lawrence, both of Evansville, Ind., September 3.

LAWRENCE E. ARNOLD to Miss Ann Holt, both of Dallas, Texas, September 8.

JAMES H. ALLEN to Miss Ruth Sanford, both of Iowa City, Iowa, August 18.

ARTHUR LEWIS MILLER, Kimball, to Miss Florence Uhl, recently.

Deaths

William Francis Drewry ☉ Richmond, Va.; Medical College of Virginia, Richmond, 1884; member of the House of Delegates of the American Medical Association in 1907; past president of the Virginia Conference on Charities and Corrections, American Psychiatric Association, Medical Society of Virginia, and the National Association for the Study of Epilepsy; member, 1924-1929, and since 1929 director of the bureau of mental hygiene, Virginia State Department of Public Welfare; member of the state board of health, 1916-1924; contract surgeon in the U. S. Army and psychiatrist to the National Guard in 1917; since 1920 member of the State Prison Board of Psychiatry; city manager of Petersburg, 1924-1928; member of the board of visitors of the University of Virginia, 1908-1916; for twenty-eight years member of the board of directors of the Petersburg Hospital; superintendent of the Central State Hospital, Petersburg, 1896-1924; aged 74; died, October 19, of carcinoma of the prostate.

Ray William Matson ☉ Portland, Ore.; University of Oregon Medical School, Portland, 1902; assistant clinical professor of medicine at his alma mater; member of the American Association for Thoracic Surgery and the American Climatological and Clinical Association; member of the executive committee of the National Tuberculosis Association; medical director of the Portland Open Air Sanatorium, Milwaukie; on the staffs of the Veterans' Administration Facility, Good Samaritan and Multnomah County hospitals; aged 54; died, September 12, as the result of an automobile accident.

George Barclay McCallum, Monroe, Mich.; University of Michigan Medical School, Ann Arbor, 1880; College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, New York, 1881; member of the Michigan State Medical Society; past president and secretary of the Monroe County Medical Society; aged 79; formerly on the staff of the Mercy Hospital, where he died, October 1, of coronary thrombosis.

Shirley Quincy Elmore ☉ Major, M. C., U. S. Army, Fort Logan, Colo.; Creighton University School of Medicine, Omaha, 1907; served during the World War; entered the Medical Corps of the U. S. Army as a captain in 1920 and in 1929 was promoted to major; aged 53; died, August 7, of coronary thrombosis, while aboard a boat bound for Honolulu.

Elijah McCulloch Harris, Russellville, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1887; member and life counsellor of the seventh district of the Medical Association of the State of Alabama; past president of the Franklin County Medical Society; aged 72; died, September 26, of angina pectoris.

William Emilus Hart ☉ Elyria, Ohio; Western Reserve University Medical Department, Cleveland, 1886; past president and secretary of the Lorain County Medical Society; served during the World War; on the staff of the Elyria Memorial Hospital; aged 72; died, September 23, of heart disease.

George E. Welch, Palatka, Fla.; Kentucky School of Medicine, Louisville, 1884; formerly member of the fifth district of the state board of medical examiners, mayor and bank president; aged 75; died, September 15, in a hospital at Jacksonville, as the result of cerebral hemorrhage and fracture of the hip.

Edward True Alford ☉ Waterloo, Iowa; Rush Medical College, Chicago, 1901; fellow of the American College of Surgeons; attending surgeon to the Presbyterian, Allen Memorial and St. Francis hospitals; aged 59; died, September 22, in West Palm Beach, Fla., of heart disease.

John Elwell McQuain, Spencer, W. Va.; Louisville (Ky.) Medical College, 1888; member of the West Virginia State Medical Association; served during the World War; aged 65; superintendent of the Spencer State Hospital, where he died, September 19, of cirrhosis of the liver.

Annie Lee Hamilton, Sandwich, Mass.; Woman's Medical College of the New York Infirmary for Women and Children, 1898; member of the Massachusetts Medical Society; aged 70; died, September 23, in Jamaica Plain, of chronic myocarditis and cerebral hemorrhage.

Henry Thomas Obuchowski ☉ Newark, N. J.; Tufts College Medical School, Boston, 1925; on the staffs of the Newark City Hospital, St. James' and Presbyterian hospitals; aged 34; died, August 8, in St. Francis Hospital, Hartford, Conn., of subacute bacterial endocarditis.

Robert Alexander McReynolds, McRoberts, Ky.; Memphis (Tenn.) Hospital Medical College, 1906; member of the Mississippi State Medical Association and the Kentucky State Medical Association; aged 49; died, September 8, of coronary thrombosis and hypertension.

Emanuel Frederick Oehler ☉ St. Louis; St. Louis University School of Medicine, 1906; aged 56; on the staffs of the Missouri Baptist Hospital and the Deaconess Hospital, where he died, September 7, of a streptococcal infection, contracted while operating on a patient.

Gerald Marvin Buchanan, Scotch Plains, N. J.; Vanderbilt University School of Medicine, Nashville, Tenn., 1909; on the staff of the Bonnie Burn Sanatorium; aged 52; died, September 18, in the Protestant Hospital at Nashville, of acute appendicitis and peritonitis.

Gustave Herman E. Starke, Tupper Lake, N. Y.; University of the City of New York Medical Department, 1889; member of the Medical Society of the State of New York; aged 75; died, August 23, in Phoenicia, of cerebral hemorrhage and arteriosclerosis.

William C. Mitchell, Bradford, Ill.; St. Louis College of Physicians and Surgeons, 1904; served during the World War; aged 59; died, September 21, in the Veterans' Administration Facility, Hines, of lethargic encephalitis, parkinsonian syndrome and bronchopneumonia.

Daniel Robbins Nettles, Peterman, Ala.; Medical College of Alabama, Mobile, 1901; member of the Medical Association of the State of Alabama; president of the Monroe County Medical Society; aged 57; died, September 13, in Clearwater, Fla., of heart disease.

Walter Owen Allen, Detroit; Indiana University School of Medicine, Indianapolis, 1921; member of the Michigan State Medical Society; aged 43; died, September 19, in the Parkside Hospital, of cellulitis of the abdominal wall following an appendectomy.

Harry Alfred Halgren, Watertown, Minn.; University of Minnesota Medical School, Minneapolis, 1897; member of the Minnesota State Medical Association; owner of the Cottage Hospital; aged 64; died, September 15, of arteriosclerosis and heart disease.

Erskine Patrick Odeneal ☉ Gulfport, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1892; served during the World War; aged 62; died, August 3, in the Touro Infirmary at New Orleans, of carcinoma of the head of the pancreas.

Robert Gill Reed, Cincinnati; Pulte Medical College, Cincinnati, 1889; at one time professor of otology at his alma mater; formerly on the staff of the Bethesda Hospital; aged 73; died, September 17, of multiple sclerosis and cerebral hemorrhage.

Jefferson D. McCullough, Columbus, Miss.; Medical College of Alabama, Mobile, 1888; formerly member of the state legislature; at one time city health officer; aged 73; died, September 8, in the Fite Hospital, of an abscess and diabetes mellitus.

Michele Nigro, Medford, Mass.; Harvard University Medical School, Boston, 1915; member of the Massachusetts Medical Society and the New England Pediatric Society; aged 51; died, August 3, of acute myocarditis and coronary thrombosis.

Henry Shelby McKenzie, Kansas City, Kan.; Kansas City (Mo.) Hahnemann Medical College, 1909; Eclectic Medical University, Kansas City, 1911; member of the Kansas Medical Society; aged 49; died, in September, of myocarditis.

Daniel Chauncey Dye, Utica, N. Y.; University of Michigan Medical School, Ann Arbor, 1885; veteran of the Spanish-American War; on the staff of St. Elizabeth Hospital; aged 74; died, August 31, of chronic myocarditis.

James Kingsland Morange Perrine, San Francisco; Hahnemann Medical College and Hospital of Philadelphia, 1893; served during the World War; aged 62; died, August 30, of coronary occlusion and arteriosclerosis.

James Henry Haslett, Phelps, N. Y.; University of the City of New York Medical Department, 1886; member of the Medical Society of the State of New York; aged 71; was found dead, September 2, at Sodus Point.

Harvey Ellsworth Hall, La Junta, Colo.; Rush Medical College, Chicago, 1890; served during the World War; health officer of La Junta district in Otero County; aged 70; died, September 18, of cerebral hemorrhage.

Henry Watkins Anderson, Covington, Va.; Baltimore Medical College, 1883; member of the Medical Society of Virginia; formerly councilman and county coroner; aged 78; died, September 4, of thrombosis.

William H. W. Sale, Covington, Tenn.; Tulane University of Louisiana Medical Department, New Orleans, 1896; member of the Tennessee State Medical Association; aged 62; died, August 30, of peritonitis.

Francis Xavier Zinger, Detroit; Detroit College of Medicine, 1907; member of the Michigan State Medical Society; aged 51; died, September 2, in the Providence Hospital, of carcinoma of the pylorus.

Edward Houston Hice, Rock Spring, Ga.; Chattanooga (Tenn.) Medical College, 1894; member of the Medical Association of Georgia; aged 65; died, August 24, in a hospital at Chattanooga, Tenn.

Smith McMullin ☉ Yuba City, Calif.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1900; aged 69; died, August 9, in the Southern Pacific Hospital, San Francisco.

Stephen Farrar Dunn, Wilmington, Vt.; University of Vermont College of Medicine, Burlington, 1904; member of the Vermont State Medical Society; aged 57; died, September 3, of pneumonia.

Charles Coyne Elliott, Leicester, England; Western University Faculty of Medicine, London, Ont., Canada, 1900; formerly a medical missionary in China; aged 56; died, August 10, of carcinoma.

Ralph Coffey Walker, Portland, Ore.; University of Oregon Medical School, Portland, 1904; member of the American Roentgen Ray Society; aged 56; died, October 1, of cerebral hemorrhage.

Davis L. Field, Jeffersonville, Ind.; University of Louisville (Ky.) School of Medicine, 1868; formerly health officer of Jeffersonville; aged 90; died, September 19, of acute myocarditis.

Calvin McCarroll, Nicosia, Cyprus Island; Detroit College of Medicine, 1904; for many years a medical missionary; aged 59; died, September 9, in the Harper Hospital, Detroit, of pneumonia.

John Alexander Macleod, Kingston, Ont., Canada; University of Toronto Faculty of Medicine, 1907; on the staff of the Ontario Hospital; died suddenly, August 20, of heart disease.

James Malcolm Stewart, Katy, Texas; Louisville (Ky.) Medical College, 1897; aged 56; died, September 7, in the John Sealy Hospital, Galveston, of arteriosclerosis and heart disease.

James Forney Dungan, Exeter, Calif.; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; aged 68; died, August 30, in San Francisco, of arteriosclerosis and heart disease.

John Thompson Maloy ☉ Bedford, Iowa; Marion-Sims College of Medicine, St. Louis, 1892; president of the Taylor County Medical Society; aged 63; died, September 14, of heart disease.

William H. McKie, Wynne, Ark.; Memphis (Tenn.) Hospital Medical College, 1904; member of the Arkansas Medical Society; aged 54; died, August 31, of cirrhosis of the liver.

Hugh Walden Allan, Taos, N. M.; University of Louisville (Ky.) School of Medicine, 1910; served during the World War; aged 48; died, September 15, of pulmonary tuberculosis.

Thomas James Morgan, Covington, Ky.; Medical College of Ohio, Cincinnati, 1901; past president of the school board; aged 69; died, August 24, of chronic nephritis and myocarditis.

Frederick Henry Odendahl, St. Paul; Missouri Medical College, St. Louis, 1891; Rush Medical College, Chicago, 1892; aged 67; died, September 2, of carcinoma of the pancreas.

J. Du Bois Van Derlyn ☉ New Paltz, N. Y.; University of Maryland School of Medicine, Baltimore, 1894; aged 69; died, September 2, of chronic myocarditis and aortitis.

William D. Hankins, Birmingham, Ala.; Memphis (Tenn.) Hospital Medical College, 1896; aged 62; died, September 3, in Atlanta, of coronary occlusion and chronic nephritis.

Emil Victor Lonigo, San Francisco; University of California Medical Department, San Francisco, 1883; aged 87; died, August 17, of bronchopneumonia and myocarditis.

William Baumgarten, San Francisco; University of California Medical Department, San Francisco, 1902; aged 56; died, August 11, of chronic aortitis and arteriosclerosis.

Levi Lewis Dorr, San Francisco; Bellevue Hospital Medical College, New York, 1866; Civil War veteran; aged 94; died, September 10, of chronic myocarditis.

George W. Roberts, Wynne Wood, Okla.; Medical College of Indiana, Indianapolis, 1883; aged 79; died, August 7, in Oklahoma City, of myocarditis.

Charles Loyal Sexton ☉ Los Angeles; Cooper Medical College, San Francisco, 1895; aged 66; died, August 23, of arteriosclerosis and heart disease.

Joseph William Davis, Denver; University of Kansas School of Medicine, Kansas City, 1906; aged 57; died, September 8, of heart disease.

Simon Oltsik, New York; University of Vladimara, Russia, 1922; aged 43; was killed, August 14, when he fell as the result of an epileptic fit.

William Seymour Davis, Los Angeles; Miami Medical College, Cincinnati, 1885; aged 73; died, August 31, of carcinoma of the bladder.

Homer Clark Miller, Altoona, Pa.; Starling Medical College, Columbus, Ohio, 1898; aged 60; died, September 2, of cerebral hemorrhage.

Roy Ricketts Shafer, Rich Hill, Mo.; Barnes Medical College, St. Louis, 1902; aged 57; died, September 5, of carcinoma of the throat.

Joseph W. Enos, Chicago; Hahnemann Medical College and Hospital, Chicago, 1881; aged 76; died, October 11, of chronic myocarditis.

Van Buren McConnaughey, Hillsboro, Ohio; Ohio Medical University, Columbus, 1893; aged 72; died, August 28, of cerebral hemorrhage.

Jokichi Oguri ☉ New York; Fordham University School of Medicine, 1914; aged 60; died, August 10, of myocarditis and arteriosclerosis.

Louis Doray, Pointe du Lac, Que., Canada; School of Medicine and Surgery of Montreal, 1897; aged 60; died in July, at Montreal.

William C. Mobley, Blue Mountain, Ark.; Missouri Medical College, St. Louis, 1887; aged 76; died, July 6, of myocarditis.

Thomas McCurdy, Coaticook, Que., Canada; McGill University Faculty of Medicine, Montreal, 1889; aged 66; died, August 5.

Correspondence

"COARCTATION OF THE AORTA"

To the Editor:—In the case report by Dr. Wilmot F. Pierce on coarctation of the aorta in *THE JOURNAL*, September 15, there is the statement on page 831 at the top, "The heart rhythm was absolutely irregular." It was my impression that such a statement has become obsolete except when modified by something more definite, as suggesting sinus arrhythmia, auricular fibrillation or extrasystoles. More than 80 per cent of irregular heart rhythms may be diagnosed definitely without the use of the electrocardiogram. The second sentence following the one quoted gives the electrocardiogram reading, which states that "there was left axis deviation, simple tachycardia, and left ventricle and right ventricle extrasystoles." This seems to indicate that one must have an electrocardiogram to know whether an irregular cardiac rhythm is or is not due to ventricular extrasystoles. Too often this appears to be the case, that is, let the electrocardiogram make the diagnosis of the irregularity. The electrocardiogram has its valued place. Why one cannot base a definite opinion of cardiac irregularities on his own hearing backed up by experience, and then take an electrocardiogram to confirm it, if possible—that would be preferable. *THE JOURNAL* should set the style by not accepting any statements of the "heart rhythm being irregular or absolutely irregular." A proper physiologic cardiac diagnosis should take its place even if the electrocardiogram does not confirm the original opinion.

NATHAN FLAXMAN, M.D., Chicago.

[This letter was referred to Dr. Pierce, who replies:]

To the Editor:—The correspondent is justified in criticizing the expression "absolutely irregular" as applied to the heart rhythm. It would have been better to say "quite irregular from numerous extrasystoles." "Perpetual arrhythmia," "complete irregularity," if used at all nowadays are usually meant to imply auricular fibrillation. I have no quarrel with him over his contention that an "irregularity" can generally be diagnosed without the electrocardiogram. This should be attempted always. The electrocardiogram should be confirmatory or corrective. This was the procedure in the case reported and I regret that there was not greater care in the use of terms.

WILMOT F. PIERCE, M.D., Chicago.

"BREAST AND ARTIFICIAL FEEDING"

To the Editor:—I should like to offer a criticism of the work reported by Drs. Grulee, Sanford and Herron in *THE JOURNAL*, September 8, page 735. The authors have done a fine piece of work but I feel that they make a generalization which does not follow the results of their work when they deduce that in order "to decrease further the infant mortality of this country it must be done by encouraging breast feeding."

The authors use as material the records taken from 20,061 babies who were under the care of the Infant Welfare Society of Chicago for as long as nine months during the years 1924-1929 inclusive. The society has stations in the poorest sections of the city.

These infants, in my opinion, do not represent (as the authors claim) "a true cross section of the national urban life," for there are no corresponding data about the infants of the better hygienic or wealthier sections of the city. Nor do better mortality rates of the babies studied (as compared with "nonstation" infants in the same district) make these infants a true cross section of the national urban life. The advantage of good medical and nursing care would lower the infant mortality of any group of infants in any district.

In 1930 I published a study (*New England J. Med.* 203:626 [Sept. 25] 1930) of breast and bottle fed infants who attended well baby clinics in two different districts in the city of Boston, one "poor district" (North End) and one "better district" (Roslindale). This study included the vital statistics of 1,566 infants and a detailed study (nutrition, development, frequency of infection and presence of deficiency diseases) of 217 infants. Both groups were followed for a period of one year.

In the "poor district" the results were consistent with those reported by Drs. Grulee, Sanford and Herron. The bottle fed infants had a mortality rate seven times that of the breast fed infants. The incidence of infection favored the breast fed by a ratio of 8 to 5. The clinic infants had a mortality rate of about one-half the mortality rates among the nonclinic infants in the same district.

In the "better district" the results were strikingly different. The bottle fed infants compared favorably (to say the least) with the breast fed infants in nutrition, development, presence of deficiency disease, and mortality rates. Also the bottle fed infants had less incidence of infection than the breast fed infants.

I found that the mothers in the "poorer district" were "sold" on the idea that breast feeding was best for the infant and bottle feeding was not considered until the breast fed infant did poorly. As a result the bottle fed infant in this district started with a distinct disadvantage. Again lack of cooperation (often the father would not permit the use of any sugar in the milk; water and sugar formulas were used) and faulty technique and procedure in preparing and feeding the formula, plus improper hygiene (overcrowding and so on) gave the bottle fed infant a definite disadvantage.

In the "better district," although the medical care and nursing care were the same as in the "poorer district," the better economic and hygienic conditions with a higher degree of intelligence and uniform cooperation resulted in the group of bottle fed infants comparing favorably with the breast fed infants.

I feel that it is no longer a question of breast or bottle feeding but one of proper nursing and medical care plus intelligent cooperation from the parents, plus proper hygienic and economic conditions. Drs. Grulee, Sanford and Herron prove what I have suggested before, that in a "poorer district" the bottle fed infant is at a distinct disadvantage as compared with the breast fed infant.

Finally, I suggest that the infant mortality of this country will be decreased by improving the hygienic and economic conditions of the poorer sections of the cities and by a program of persistent "infant education" with special emphasis on correcting the "breast feeding at any price" attitude among these people, so that there will be less delay in bottle feeding (in whole or in part) when there is a deficient or defective breast milk.

MANUEL M. GLAZIER, M.D., Boston.

[This letter was referred to Dr. Grulee, who replies:]

To the Editor:—Apparently from Dr. Glazier's remarks, we are talking about two different things. The group of artificially fed infants, as explained in the text, were fed artificially from the very first and these we followed for a period of nine months. These children were practically all first seen in the first month of life. The cases which he refers to would be included in our second group, or those partially breast fed. In that group there were two classes of cases: first, those that were simply complemented because of insufficient supply of breast milk and, second, those who were breast fed at first and artificially fed later. It is true that these children were in the poorer districts and that they were subject to more infection than we would expect to find among the better classes of the community.

On the other hand, the death rate was extremely low, about one fourth of the general death rate of the community at large.

I am under the impression that the general death rate in Boston is higher than it is in Chicago. After all is said and done, the fact still remains that for those children who are entirely breast fed the death rate was so low as to be near the vanishing point and certainly I cannot see how Dr. Glazier can claim that his statistics in any group of artificially fed children, under any conditions, are better than those for the group of breast fed children in our paper.

Dr. Glazier objects to the statement that "this is a true cross section of national urban life." It is a true cross section only perhaps so far as nationality is concerned and was meant to convey that impression. Then, as far as mortality is concerned, the results are far better than those obtained throughout the city for the same age group. The report of Dr. Glazier is inconclusive because of the small number of cases which he has reported. Certainly he cannot claim much for his statistics other than those for the 217 of the detailed study.

In conclusion, Dr. Glazier states "that infant mortality of this country will be decreased by improving the hygienic and economic conditions of the poorer sections of the cities and by a program of persistent 'infant education' with special emphasis on correcting the "breast feeding at any price" attitude among these people." If Dr. Glazier feels that way after reviewing our statistics, I am sure I do not know how we can persuade him that he is wrong. To me these statistics are very conclusive evidence that breast feeding does protect the child under adverse conditions. In my opinion it is utopian to think that such adverse "hygienic and economic" conditions as the poor of large cities now experience will be overcome at any time in the near future. CLIFFORD G. GRULEE, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF SYPHILIS WITH TUBERCULOSIS

To the Editor:—I have a woman patient 30 years of age whose sputum is positive for tuberculosis and whose temperature ranges between 99.5 and 100.5 by mouth. Six weeks ago iritis developed and a blood Wassermann reaction was four plus. An attempt was made to treat her with a soluble bismuth compound intramuscularly and the temperature was increased and the patient complained of pain in the gums. A few days later an injection of mercuric salicylate intramuscularly was given and this time the temperature was not increased but the patient had severe pains about the gums and marked salivation. Four days later I decided to try an intravenous injection of 0.3 Gm. of nearsphenamine. This resulted in a chill, and the temperature rose to 102. As a result of all three treatments the eye condition has cleared up to a marked degree, but I am wondering what to do for her as far as her syphilitic condition is concerned. She obviously is not reacting well to bismuth or mercury compounds or nearsphenamine, possibly on account of her pulmonary condition. Also on account of her tuberculosis, I am afraid to give her potassium iodide. In spite of both diseases the patient feels fine, is free from any pain or discomfort, has a good appetite and is not losing in weight. She has had the pulmonary condition for about two and a half years, but for the past year and a half examination of the sputum has been negative until the iritis developed. What treatment would you advise at the present time? Please omit name. M.D., New York.

ANSWER.—The treatment of syphilis coincident with tuberculosis depends, in general, on the status of the two disease processes. The inquiry does not supply sufficient information as to the age of the syphilitic infection, though it may be presumed that the occurrence of the iritis, if indeed it is syphilitic, would place the spirochetal infection within the first two or three years of its course. It should be noted also that the inquirer does not mention the confirmation of the positive serologic test by repetition and by the use of at least two laboratory technics. This is important, because false positives are known to occur in tuberculosis in the absence of syphilis, to say nothing of the possibility that a single four plus Wassermann reaction may be the result of a laboratory error. If the iritis is nonsyphilitic instead of syphilitic and the syphilitic infection is of prenatal type or a well established latency, there is less

demand for intensive antisyphilitic treatment from the standpoint of the syphilis, and the open tuberculosis as such should receive the major portion of attention. The merits of these various situations have been considered in the literature by Petersen and Hecht, Habliston, Schlesinger, Landis, Gloyne and particularly in a valuable study by Gallant. The work of these observers is summarized in Moore's and Stokes's (second edition) textbooks. Gallant's study of 346 cases showed clearly the unfavorable effect of the untreated syphilis on tuberculosis, the mortality in cases untreated for syphilis being 57 per cent and that in those who received treatment for syphilis 21.5 per cent. Coincidentally, improvement under treatment for syphilis rose from 20.9 per cent to 51 per cent. Using the National Tuberculosis Association's classification, Gallant found that the best results with treatment of the syphilis occurred in the minimal group, and the poorest results in the advanced cases. Moore believes that the relatively less intensive treatment used by physicians in charge of tuberculosis sanatoriums and the advantages of sanatorium care largely explain the superior results of this type of management as compared with ambulatory and outpatient treatment. He recommends that open tuberculosis be placed under sanatorium conditions as rapidly as possible when treatment for syphilis is indicated. Gallant and Stokes both point out that very active tuberculous disease with high temperature is made definitely worse after antisyphilitic treatment, and the terminal stages of tuberculosis with cachexia are contraindications. On the other hand, Gallant found that even the increased tendency to reaction was not often harmful even in advanced cases, and that antisyphilitic treatment apparently reduced the death rate among them none the less. Gallant found the arsenicals in general to be responsible for increasingly favorable results. Stokes prefers nearsphenamine to arsphenamine, and Gallant reduces the arsenical dosage to one-half or one-third the usual amount. The difficulty with the administration of bismuth compounds in the case described may be due to neglect of mouth prophylaxis or to initial overdosage, for bismuth should, in general, be well tolerated by the tuberculous patient and is easily adaptable to the special difficulties of treatment. The effect of treatment on the eye in this case does not necessarily prove the etiology of the iritis to be syphilitic, although of course it suggests it.

It is advised that after a more careful attempt to determine the status of the syphilitic infection this patient be, if possible, given the benefit of sanatorium care, that lower nearsphenamine dosage be employed and that bismuth compounds likewise in materially reduced dosage be used instead of mercury for the heavy metal phase of the treatment.

VARICOSE ECZEMA WITH RINGWORM INFECTION

To the Editor:—A woman, aged 76, whose family and medical history are otherwise negative, has been suffering from varicose veins of the legs for many years. Occasionally a varicose ulcer has developed on one of her legs, which always healed without much difficulty. About nine months ago this ulcer again reappeared in a mild form. This time there was a dermatitis of the skin surrounding the ulcer area. This gradually extended up toward the knee. It would improve considerably and then would suddenly reappear over night and was occasionally associated with small blebs. About four months ago she began to notice a slight dermatitis associated with marked itching. This was all over her body, particularly the arms, neck and legs. This varied in intensity from day to day and when it had nearly disappeared would again reappear over night in increased severity. At present she has this dermatitis over the entire body, with considerable induration of the skin of the forearms. She has no other symptoms than itching due to the dermatitis. Physical examination revealed nothing except the skin eruption. The urine is normal. The blood pressure is 116 systolic, 84 diastolic. The blood sugar is 87 per cent; leukocytes, 12,000; polymorphonuclears, 38 per cent; small lymphocytes, 35 per cent; large lymphocytes, 3 per cent; eosinophils, 24 per cent. Kindly express an opinion as to the diagnosis and advise treatment. Please omit name. M.D., Pennsylvania.

ANSWER.—Varicose eczema, with the possibility of a superimposed ringworm infection, is not rare. The generalized, itching dermatitis, however, together with the finding of 24 per cent eosinophils may suggest a sensitization reaction on an allergic basis. It must be remembered, however, that a great many skin diseases show eosinophilia. Large doses of calcium gluconate and slow intravenous injection of 10 per cent sodium thiosulphate may alleviate the symptoms, provided further sensitizations do not occur. One should be sure that the original lesion around the ulcer is not maintained by a ringworm infection, in which case suitable treatment should be instituted. The possibility of a chemical dermatitis from salves applied to the ulcer, which may provoke a generalized reaction, should also be considered. The patient may benefit by consulting a competent dermatologist who is interested in the cutaneous phenomena of allergy.

PHYSIOLOGY OF LACTATION

To the Editor:—Will you kindly explain the cause and give the treatment of the following phenomenon: A girl, aged 18, can express an ounce or more of milk from each breast at will. This condition has existed for five months to the patient's knowledge and may have existed longer. There is no appreciable evidence of glandular disturbance; she is not pregnant and is apparently normal in all other respects. Please omit name and city.

M.D., District of Columbia.

ANSWER.—The cause of the apparently spontaneous lactation by both male and virgin mammals, otherwise normal, has not been determined. Lactation has been induced experimentally in both male and virgin laboratory mammals in a number of different ways, the chief one being the injection of extracts of the anterior lobe of the hypophysis which contain the active principle termed prolactin. Lactation has been observed experimentally in animals after producing lesions of the ovary, which tends to confirm the suspicion of some older clinicians that "ovarian irritation" was responsible for lactation in a virgin. In most cases in either sex spontaneous lactation is the result of a mechanical stimulus applied to the breast, the usual and most potent stimulus being sucking. It rarely occurs associated with acromegaly, pituitary enlargement, uterine myomas and pseudocyesis. It has occurred as a sequel of endemic encephalitis. In the male, spontaneous lactation (colostrum or milky fluid) has occurred associated with chorionepithelioma of the testis and also hypernephroma and pineal tumor. The most recent reference is by Krestin (*Lancet* 1:928 [April 30] 1932).

There is no satisfactory treatment. From the aspect of hormone therapy, lactation in the rabbit may be inhibited by large doses of estrogenic substance. The luteinizing fraction of pregnancy urine inhibits lactation in nursing mice. Theoretically, progestin (the corpus luteum principle) should also be effective. However, there is so much species variation in the ovarian-pituitary-mammary gland interrelationship and so little is known definitely about this interrelationship in man that any hormone therapy would be entirely experimental. Further, it is possible in view of the age of the patient that hormone therapy might do harm. Roentgen therapy over each breast has been used in cases of spontaneous lactation and galactorrhea, definite diminution of secretion being obtained. How lasting the effects of roentgen therapy would be, or its effect on future functioning of the gland, is not answered in the literature. The simple treatment of a tight binder with boric acid dressing of the nipples to prevent infection should be tried.

CONTACT DERMATITIS FROM WEEDS

To the Editor:—A patient of mine, a farmer, has a yearly rash, which covers his face, his forehead and the front of his neck. It is characterized by intense burning and itching. He states that the rash comes on each year about the first of August when he starts weeding his potatoes and, if he continues to work among the weeds, continues until frost kills the weeds off. When I saw him the region outlined was subacutely inflamed and was "weeping" considerably. Can you give me any idea as to the nature of the weeds that might cause this? What can be done in the way of treatment to give permanent relief? Please omit name.

M.D., Massachusetts.

ANSWER.—The type of case cited is not uncommon. It is undoubtedly an instance of contact dermatitis, most likely due to contact with a plant. This form of dermatitis constitutes a hypersensitiveness that does not fit in the group commonly called allergy. The irritation is usually due to the ether-soluble fraction of the plant or to its pollen rather than to the protein fraction. Contact dermatitis caused by hay fever plants is usually present in the absence of any hay fever symptoms. An individual may be sensitive to almost any plant. The various species of ragweeds have been known to cause dermatitis rather frequently. In the region of the inquirer the short ragweed (*Ambrosia elatior*) is the only species of ragweed present in any abundance. It should be remembered, however, that almost any plant growing in the season mentioned may be responsible. The potato vine must not be disregarded.

In order to make a definite diagnosis of the causative agent, the following procedure is advised: A specimen of every weed and plant in the field should be obtained. A small piece of the leaf of each plant should be placed on a separate piece of gauze about an inch square. If the leaf is too dry, it may be moistened with liquid petrolatum. This "patch" is applied with the leaf next to the surface of the skin. The gauze is then covered with a square of oiled silk and the patch is fastened to the skin with adhesive tape. A number of such patches may be applied to the back at one time. The patches are removed in from twenty-four to forty-eight hours. If there is marked irritation underneath any of them it may be removed

sooner. A positive reaction will be evidenced by a redness, going on to vesiculation and edema and accompanied by a burning and itching sensation.

When the causative factor has been determined, specific treatment is possible. This usually consists of intramuscular injections of an extract of the ether-soluble portion in almond oil. No definite strength of doses can be recommended, since that would depend on the nature of the plant, the potency of the extract and the degree of sensitiveness of the individual. One must be guided by the reaction of the patient and begin with high dilutions, as is customary in other types of desensitization. The success of such treatment is not certain, although it holds forth encouragement. Because of the technical difficulties in preparation of such an extract it would be advisable to have it prepared by an allergist or a laboratory accustomed to prepare such extracts.

ALLERGY TO PIN OAK

To the Editor:—Will you please inform me as to the usual allergic manifestations from pin oak and just how they are caused, other than by contact? Is this form of allergy common and has it any age preference? What treatment would you suggest? Please omit name.

M.D., Philadelphia.

ANSWER.—Pin oak (*Quercus palustris*) is only one of the many varieties of oak that are found in North America. In the United States there are about sixty-five different species. The other important varieties of oak are the red, scarlet, black, white and post oak.

Pin oak, in the section east of the Mississippi River and north of Tennessee and North Carolina, pollinates from about the 10th to the 26th of May. Other varieties of oak pollinate for longer periods and the post and black oak throw out their pollen as late as about the middle of June, so that oak pollen is in the air from about May 10 to about June 15.

The various species of oak tree are probably the most important causes of tree hay fever and the symptoms appear at the time of pollination of the various kinds of oak. A patient who is hypersensitive to one variety of oak is usually also susceptible to the other species. About 5 to 10 per cent of all hay fever is due to tree pollen. A considerable proportion, perhaps as high as 40 per cent who are sensitive to tree pollen develop bronchial asthma.

There seem to be no age preference.

The treatment of hay fever and bronchial asthma due to any variety of oak is similar to that due to the pollen of grasses and ragweeds; that is, complete skin tests are done, including not only the various pollens but also tests, if possible, for the epidermals, foods and miscellaneous proteins; and injections of mixed oak pollen extract should be started about three months before the season, about March 1, and from fifteen to twenty-five injections should be given with gradual increase in strength so that the maximum dose may be given just before May 10.

The extracts with minute directions may be purchased from several different pharmaceutical firms. It is important to follow the instructions so as to avoid possible reactions that may occur after the injections.

DIPHTHERIA

To the Editor:—Is there any way one can tell whether or not a child who has had diphtheria antitoxin did or did not have diphtheria? How soon, in your opinion, after the antitoxin is given will a culture show negative?

J. L. WILLIAMSON, M.D., Burnet, Texas.

ANSWER.—The cultivation of diphtheria bacilli from the local lesion is the only certain way of telling that a child has diphtheria. After recovery the bacilli often persist, in which case their presence strongly suggests that the preceding disease was diphtheria. It may happen that a carrier of diphtheria bacilli who is immune and gives a negative Schick reaction may develop tonsillitis from other forms of infection. Here the cultivation of diphtheria bacilli would not be proof that the disease was diphtheria. It is always hazardous to predict when negative cultures will be secured in an individual case. The giving of diphtheria antitoxin does not directly influence the bacilli or determine the occurrence of negative cultures. Observations in large series of cases have indicated that after diphtheria about 20 per cent become negative during the first week and that about 50 per cent of those which are positive at the beginning of each subsequent week become negative during that week. About 70 per cent become negative three weeks and about 85 per cent four weeks from the onset of the disease. Bacilli can be cultivated from but few after six or seven weeks. A few become persistent carriers for an indefinite time.

TREATMENT OF HYPERTENSION

To the Editor:—A man, aged 54, has a blood pressure between 240 and 290, causing severe headaches and inability to do any type of work although he was always active up to the time of his first attack, five years ago. I have been unable to find a cause for this hypertension. All different types of nitrites have been tried; a salt-free diet has been rigorously enforced, and his weight has been brought down from 210 pounds (95 Kg.) to 145 pounds (66 Kg.) by observance of this diet. Phlebotomy has been the only real relief given, and it is done at monthly intervals at least. During his last stay in the hospital I used magnesium sulphate 25 per cent, 10 cc. intravenously, which gave him relief for a short time but almost caused death while being injected. The only diagnosis that I have been able to make is essential hypertension. Have you any idea what effect the use of ergotamine tartrate would have? Kindly omit name.

M.D., New York.

ANSWER.—It is unfortunate that the diastolic pressure of this patient was not stated. It must be repeatedly and emphatically reiterated that from the points of view of diagnosis, prognosis and therapy, the diastolic tension is essential to a clear understanding of the circulatory difficulty. As regards the cause of this patient's excessive hypertension, information is lacking with regard to pertinent questions of his history. It may be stated as a generalization that probably hereditary and familial factors of physical and emotional constitution are the most common etiologic factors in hypertensive arterial disease. However, the instances in which the disease is due to but one factor are exceptionally rare; almost invariably there are numerous superimposed insults to the circulatory apparatus (Stieglitz, E. J.: *Arterial Hypertension*, New York, P. B. Hoeber, 1930). Commonly the etiologic factors have ceased to exist and are no longer operative by the time the hypertensive disease is discovered, for the onset of this disease is insidious, gradual and as a rule wholly asymptomatic. The disease tends to progress continuously despite the disappearance of the original initiating factors, for, once started, the pathogenic changes are progressive and largely self-perpetuating. Therefore it is in the past that one must look for the probable etiologic factors of the disease. Just when these were operative can usually be approximated by a careful analysis of the patient's history. In this instance the onset was probably from ten to twenty years ago.

From the query it may be assumed that either extensive sclerotic changes have already occurred or that some active but as yet undiscovered etiologic factor is still operative. The failure of all the various nitrites and other vasodilators to reduce the arterial tension justifies this conclusion. A remote possibility is that this rigid hypertension is due to coarctation of the aorta; this could be readily ascertained by observation of the arterial tension in the legs as contrasted with that in the arms. The patient's age, however, makes this possibility extremely remote. If extensive arteriosclerosis has already occurred, none of the vasodilating drugs can be expected to accomplish much. In fact, as all his symptoms appear to be cerebral, violent vasodilatation may be most precarious; it has been shown that amyl nitrite may increase the intracranial tension with a rise in spinal fluid pressure (Hare, C. C.: *Bull. Neurol. Institute of New York* 3:513 [March] 1934). Hypertonic dextrose solution injected intravenously may cause a transient rise in spinal fluid pressure, followed by a fall for two or three hours and then a rise to above the original level (Masserman, J. M.: *Effects of Intravenous Administration of Hypertonic Solutions of Dextrose*, *THE JOURNAL*, June 23, 1934, p. 2084). The risks of magnesium sulphate, when given intravenously in hypertonic solution, are sufficient to preclude its justification in this type of patient. Acute cardiac reactions are not uncommon (Adair, F. L., and Stieglitz, E. J.: *Obstetric Medicine*, Philadelphia, Lea & Febiger, 1934, p. 434). Hirschfelder has pointed out the dangers of increased blood magnesium, which may be responsible for coma (Hirschfelder, A. D.: *Clinical Manifestations of High and Low Plasma Magnesium*, *THE JOURNAL*, April 7, 1934, p. 1138). Ergotamine tartrate cannot be expected to accomplish anything for this patient and even may be injurious. The reduction of the patient's weight, if not carried too far, is certainly desirable. Not knowing how tall he is, one cannot say how marked his obesity was. Phlebotomy, if not too extensive or repeated too frequently, is quite justified so long as repeated examinations of the blood are made so that any secondary anemia may be prevented. In the long run such therapy is usually unwise, for the presence of an anemia is markedly aggravated with the progressive changes of the disease and the severity of the cerebral, cardiac and renal impairment. In this particular instance blood volume studies might be illuminating, although changes in blood volume are almost never a factor in long continued hypertensive disease.

If the assumptions are correct, and they can be no more than assumptions from the data at hand, the most satisfactory

therapy for this patient should be the administration of mild, nontoxic sedatives, such as the bromides, over a relatively long period. These should aid in obtaining some symptomatic relief and if the arteriosclerosis is as extensive as it appears to be, symptomatic relief and reassurance are all that one may hope to accomplish.

ANTIPILOGISTIC ACTION OF ANALGESICS

To the Editor:—In recent years a note of caution has been sounded in regard to massive doses of salicylates on the ground that their analgesic effect on rheumatic arthritis was due to their depression of the reactivity of serous surfaces, the implication being that this depression of defensive function might extend to the endocardium and predispose to an endocarditis. Does this depressant action of the salicylates extend to other inflammatory processes? I recently observed a patient with a boil on his face—in fact, a hydra-headed monster that might more accurately be termed a carbuncle. One-half grain (0.03 Gm.) doses of codeine had almost no effect on the pain, but 10 grains (0.65 Gm.) of acetylsalicylic acid would give complete relief for three or four hours. It was interesting to note that not only pain but local tenderness was greatly diminished while the salicylates were in effect. It seemed unlikely that this was purely a central nervous system effect, as codeine was ineffective. On the other hand, if the effect was due to a depression of the inflammatory reaction with consequent diminution of tension it was a microscopic action, as the degree of redness and swelling appeared unchanged. The question naturally arises as to whether such a presumed depression of normal tissue response is justified for the sake of relieving pain. Is one thereby prolonging the process of necrosis and liquefaction and perhaps interfering with normal protective mechanisms? Please omit name.

M.D., Massachusetts.

ANSWER.—It is an interesting fact, an instance of which is shown in the effect of the 0.65 Gm. dose of acetylsalicylic acid on the boil, that analgesics also have an antipilogistic action. This, however, is true also of opiates such as codeine; but it would have required a larger dose than the 0.03 Gm. dose employed to demonstrate this action. That such an effect is obtainable from codeine is illustrated by the observations recently made regarding the efficiency of this agent in the treatment of coryza (Harold S. Diehl, 1933). The effect is probably similar to that which occurs when a person who has a cold and a running nose, requiring continued use of the handkerchief, goes to sleep: the discharge almost ceases during the sleeping hours. It is doubtful that this diminution of the inflammatory reaction is sufficient in degree to be dangerous, but it is evident that it does not really help in overcoming the infection.

MEMBRANES AND PLACENTA OF QUINTUPLETS

To the Editor:—As no doubt others have done, I wish to call your attention to the report on the Dionne quintuplets by Dr. Dafeo in *THE JOURNAL*, September 1. The question arises in my mind as to how it was possible for the last two babies to be born with membranes intact and yet for the placenta and cords to remain unseparated in the uterus, as the report would seem to suggest.

L. V. BLUM, M.D., Wilmington, Del.

ANSWER.—It is possible for a fetus to be delivered in an intact amniotic sack, the amnion having stripped completely away from the chorion. Such an occurrence has often been noted in early abortions, in which event the cord usually breaks off with the amnion at the placenta. In the later months such a condition is much rarer and then usually the amnion is stripped off of the cord to the baby's navel, there being an accumulation of the fluid between the amnion and Wharton's jelly.

MYCOTIC DERMATITIS

To the Editor:—I have been treating a case of mycotic dermatitis in the axilla for eight months without a complete cure. The medication that has given the most relief is the salicylic acid, sulphur and zinc oxide ointment. However, this does not clear it up in the cases of the axilla. What would you suggest? Ultraviolet rays and x-rays have been of no value. Please omit name.

M.D., Minnesota.

ANSWER.—The diagnosis of mycotic dermatitis implies that the diagnosis has been confirmed by the demonstration of fungi in scrapings from the axilla. Epidermophyton inguinale is frequently the cause of such a dermatosis, although many other fungi have been reported as causing the disease. The upper part of the thighs and under pendulous breasts are also common sites for the appearance of this condition. The use of salicylic acid and sulphur in strengths varying from 1 to 5 per cent is frequently efficient, although a solution of sodium thiosulphate (10 to 15 per cent strength), sopped on two or three times a day, may be more comfortable than an ointment. Care must be exercised not to apply keratolytics which are too strong to the axillae, groin or under the breasts, because a

secondary dermatitis may develop in these areas from comparatively weak applications. A solution of benzene containing 2 per cent iodine painted on once a day or calamine lotion to which 0.005 per cent phenol has been added is useful in the "finishing off" of treatment. In obese individuals a restriction in the amount of sugar and other carbohydrates ingested is often of value, as Caro has shown that fungi produce dermatitis in the axillae, groin and under the breasts more frequently in those patients in whom the sugar content of the sweat is higher than normal, although no evidence of diabetes mellitus can be demonstrated.

HEADACHES AT MENSTRUAL PERIOD

To the Editor—I have a patient aged 34 who has been having headaches one week before each menstrual period for the past seven and one half years. She has one child, aged 14 but has had no other pregnancies. The headaches are sometimes frontal and sometimes temporal but never in the temporal and frontal regions at the same time. Physical examination reveals no abnormalities and no evidence of disease. Wassermann and Kahn tests are negative. Blood count, urine and metabolism rates are normal. An eye, ear and nose consultant found no pathologic changes. Roentgen examination of the sella was not made. Before treatment was started the patient had frequent headaches which apparently were not connected with menstruation. These have been overcome by the removal of worry and by suggestive therapy. The first month that an anterior pituitary like substance (followed by theelin) was given there was no headache at all. The three successive months the headache was markedly improved, the fourth and fifth months of this treatment the headache became severe again, always occurring from five to seven days before the onset of the menstrual period. Following administration of the anterior pituitary like substance and theelin the scanty menstruation became normal in amount. I have been unable to unearth any cause of revolt against menstruation. Elimination diets had no influence on the headache there is no other manifestation of allergy. I shall appreciate any suggestion concerning diagnosis and treatment. Please do not publish my name.

M D, Texas

ANSWER—In most of the cases in which endocrine products have relieved the type of headaches described in the query, the results have been about the same as those noted in this case. Other glandular products will hardly prove more successful. The headaches in this case may be related to the migraine headaches, which are extremely difficult to relieve. A drug that has proved to be helpful in many cases of migraine is ergotamine tartrate, though care should be exercised that ergotism is not produced. There is some difference of opinion as to whether ergotamine tartrate will relieve headaches that are not of migraine origin, but the drug has definitely proved to be helpful in cases of headache not classed as migraine. Gynergen is the proprietary name for ergotamine tartrate, it is used mainly in obstetrics and gynecology. The drug is best given intramuscularly, subcutaneously or intravenously, but it may also be taken by mouth. The drug does not cure or prevent the migraine type of headaches but it frequently brings about quick relief from attacks.

REMOVAL OF LIME FROM ALUMINUM KETTLE

To the Editor—I should like to know if there is anything that will remove the lime from the inside of an aluminum teakettle.

M D, Indiana

ANSWER—An inquiry was made of the Aluminum Company of America. The firm replied:

There are two general methods of removing lime deposits from the inside of an aluminum teakettle. The simplest method is to gently heat the empty kettle over an open flame. Care must be taken, of course, that the aluminum is not overheated and melted. This treatment will frequently be adequate to cause the deposited lime to crack loose from the aluminum, so that it can be emptied out. Tapping the kettle while hot or pouring cold water into it while hot also aids in this mechanical method of removal.

In case the lime cannot be satisfactorily removed by the above method, the kettle should be partially filled with vinegar, which should be held at the boiling point until the lime has been completely dissolved, or at least softened so that it can be easily slushed out.

ANIMAL SUSCEPTIBILITY TO GONORRHEAL INFECTION

To the Editor—Would it be possible to implant the discharge that is suspected of gonorrhea into the eye, penis or vagina of a rabbit, dog or kitten? All the tests that I have ever read about are not simple enough and I do not remember that I ever read anything about this test.

A C MULLER, M D, Sacramento, Calif

ANSWER—The animals mentioned are not susceptible to the gonococcus and consequently implantation of a suspected discharge cannot yield information of diagnostic value.

EFFECTS OF MERCURY IMPREGNATION ON HAIR

To the Editor—One of my patients used hair tonic containing corrosive mercuric chloride and resorcinol in alcohol. The last application was about six months ago. Now when she has a test curl before a permanent wave it is found that the hair dyes intensely black. Repeated rinsing has not altered this. It seems to me probable that it is due to persistence of some of the mercury, which is oxidized by the heat. Do you know of any way to correct this?

RICHARD F. HERNDON, M D, Springfield, Ill

ANSWER—Gray human hair was tested by soaking it for five days in a 20 per cent solution of resorcinol in 50 per cent alcohol. The hair was then rinsed in water, partly dried and heated with a curling iron heated to sizzling temperature as tested by the time honored saliva method. The hair showed no change in color after heating. A second specimen of hair was soaked for the same length of time in 2 per cent solution of corrosive mercuric chloride in 50 per cent alcohol, rinsed in water, partly dried and subjected to about the same degree of heat. It turned yellow at the point heated. This rough test corroborates the correspondent's theory, but to stand criticism the test would have to be repeated at a scientifically measured temperature.

As nothing is known of the chemical combination of the mercury with the hair, no advice can be given for its removal. If a sulphur combination has taken place, as might be assumed from the fact that the sulphur content of the hair is large, then removal will be difficult. It seems probable that the patient will have to avoid any hairdressing operation that necessitates the use of heat until the hair impregnated with mercury has fallen out or has grown long enough so that the impregnated ends may be cut off. This may take another six months or more.

TREATMENT OF WARTS

To the Editor—In THE JOURNAL, September 8, page 775, is a query regarding the treatment of warts on the face. I should like to mention the results of treatments of verrucae vulgares by intramuscular injections of bismuth salicylate (Lurie Sophie A. Verrucae Vulgares, *Arch Dermat & Syph* 26:95 [July] 1932) and discussions on the same subject at the state medical convention, Delmonte, Calif., April 24-27, 1933 (*California & West Med* 39:386 [Dec.] 1933). My further observations gave an opportunity to see the disappearance of various varieties of warts (vulgaris, filiformis, plana) multiple and various in size on the face, forehead, front of the neck and on the left arm pit.

A beauty parlor operator, whose face was almost entirely covered by verrucae planae for years, received elsewhere roentgen treatments and "pills" of yellow mercurous iodide, I presume without any visible results. Two bismuth salicylate intramuscular injections cleared her face absolutely.

A school teacher had on her forehead numerous verrucae planae for five years. She also had received roentgen treatments elsewhere without success. Three intramuscular injections of bismuth salicylate gave a spectacular result.

A motion picture technician had tumor like formations of verrucae vulgares on the forehead for many years. They responded beautifully after three treatments.

A business man had a filiform like verruca the size of a large pea on the front of the neck for many years, it responded after one treatment.

A high school girl was disfigured by numerous hanging filiform like warts on her face, three treatments gave the desired result.

A school boy 12 years of age was afflicted suddenly with fifty cornified, hypertrophic, filiform warts on the left arm pit, two treatments gave a spectacular success.

SOPHIE A. LURIE, M D,
Los Angeles

FUNCTION OF THE EPIGLOTTIS

To the Editor—In the reply to a question on the function of the epiglottis in Queries and Minor Notes in THE JOURNAL, September 22, no mention was made of the conclusions of Negus.

"The original function of the epiglottis was that of shutting off the mouth from the pulmonary air tract in order that all air should pass through the nose and keep up the keenness of the olfactory sense. In Man . . . the epiglottis has ceased to have any important olfactory function."

"As regards respiration the organ has almost no function . . ."

"Its influence on deglutition is slight."

"The epiglottis, as a whole, is pressed against the base of the tongue during swallowing and does not fall back as a lid to the laryngeal aperture, as was at one time supposed. The greater part of the organ can be removed without any noticeable effect on the individual" (Negus, V E. The Mechanism of the Larynx, St. Louis, C V Mosby Company, 1929, p. 449.)

This is a reiteration of conclusions reached by the same author earlier, in his article "The Function of the Epiglottis" in the *Journal of Anatomy* (62:1 [Oct., part 1] 1927). It seems to me that the monograph by Negus (although I dislike its anthropomorphic style) would be invaluable to any one giving speech courses.

Book Notices

The Treatment of Injuries of the Head and Spine. By Jewett V. Reed, M.D. Paper. Pp. 96, with 39 illustrations by the Department of Illustration, Indiana University School of Medicine. Indianapolis: C. E. Pauley & Company, Inc., 1934.

In this monograph Reed's object is to "set forth in the shortest and simplest manner the method and procedure of treatment of injuries to the brain and spinal cord." He accomplishes his purpose. The work is divided into two parts, part one dealing with head injuries and part two with injuries to the spine. Under head injuries the author briefly reviews the pathology and probable mechanism of production of skull fractures and discusses more extensively the symptomatology and treatment. The operative treatment of compound skull fractures and of middle meningeal hemorrhage is presented in detail and well illustrated. In conclusion Reed states that the "treatment of 90 per cent or more of all head injuries is entirely a medical rather than a surgical problem." Injuries to the spine are divided into two groups, fracture and dislocations of the vertebrae that result in injury of the spinal cord and, second, injuries of the vertebral processes and bodies without cord involvement. On account of the inability to differentiate clinically between laceration and simple pressure on the spinal cord, the author advises laminectomy "as soon as the patient has recovered from shock" in all cases of spinal injury with paralysis. The treatment of fractures of the vertebrae, such as of the transverse and spinous processes, and of the bodies of the vertebrae, not complicated by paralysis, is briefly reviewed and accompanied by illustrations of a "method of obtaining hyperextension and manipulation of compression fractures of the vertebral bodies" and of a method of reduction of cervical dislocations without paralysis. This monograph is of value as a quick reference work for medical students and the physicians and surgeons who administer the immediate treatment to patients with injuries to the head and spine.

Nuevas prácticas de farmacia: Farmacotecnia. Por J. F. de Casadevante, farmacéutico. Prólogo del Dr. M. M. Maestre Ibáñez, farmacéutico de la Beneficencia Provincial. Paper. Price, 25 pesetas. Pp. 411, with 54 illustrations. Madrid: Javier Morata, 1934.

This book, written at the request of the author's numerous colleagues, aims to present accurate, reliable and rapid methods for the scientific preparation of pharmaceutical products. It does not pretend to be comprehensive but includes all that is necessary for the daily problems of the practicing pharmacist, especially methods for the preparation and conservation of medicaments. Because it is designed for the practical pharmacist, the author does not include biologic testing; but he tells

where such methods of testing may be found. The book gives the impression of having completely and satisfactorily fulfilled the aims of the author. He does not discuss therapeutics but writes purely for the pharmacist and those interested in pharmacy. A good index is included. If one may judge the condition of Spanish medicine from this treatise on pharmacy, it is modern and progressive.

Laboratory Manual of Biological Chemistry with Supplement. By Otto Folin, Hamilton Kuhn Professor of Biological Chemistry in Harvard Medical School. Fifth edition. Cloth. Price, \$3. Pp. 368, with 9 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1934.

This well known laboratory guide, beginning as a manual for medical students in Harvard Medical School, has now grown into a standard book of procedure for clinical laboratories the world over. The present edition has been rewritten in many sections and one finds many answers where questions existed in former editions. The most important additions to the book are three micro methods for the determination of sugar, non-protein nitrogen and uric acid in the blood, and a revised method for the determination of creatinine in the blood. A number of new methods have been substituted for old ones; for example, the method of Fiske and Logan for calcium and magnesium in the urine is substituted for that of McCrudden. One finds added a new method for the determination of potassium in the urine, total fixed base, ammonia and potassium in the blood, and for treatment of unclotted blood. There are numerous slight modifications in various methods and several new illustrations. One finds a few omissions, which for completeness should be included; for example, tests for sulphates, sodium and carbon dioxide combining power in the blood. The manual is so familiar as to need no general comments as to its excellence or to call attention to the fact that the methods for the most part are those which have been developed by Folin and his students. The book is interleaved with blank pages for notes.

Les syndromes ménériques. Par S. H. Mygind et Edda Dederding. No. 26, Monographies oto-rhino-laryngologiques internationales. Publiées par M. Vernet, L. Ledoux, G. Portmann, H. Aloin et M. Sourdille. Analyses en Allemand et Anglais. Paper. Price, 40 francs. Pp. 273. Paris: Les Presses Universitaires de France, 1934.

This monograph considers in detail the Ménière syndrome, covering practically every phase, both anatomic and clinical. Among the subjects discussed are the anomalies of the vestibular function, the cerebral nervous phenomena, tinnitus aurium, and the diagnosis and the treatment of Ménière's disease. The authors, especially Dederding, have done an enormous amount of experimental work. The question of the influence of water intake and its effects on various functions of the ear forms an important phase of the consideration of Ménière's disease in the present publication. There are appended summaries of the book in German and in English, and these are of great value to those who are unable to read French. A rather comprehensive bibliography is also given. The monograph is printed in large type, illustrated with a number of tables and audiometric charts, and is written in a clear, easily understood style. While some of the conclusions of the authors may not in the last analysis prove to be entirely correct, the book as a whole is a valuable contribution to the subject and should prove of definite value to the many clinicians who are confronted with the various phases of Ménière's disease.

Nursing Procedures. School of Nursing, Philadelphia General Hospital. Fifth edition. Cloth. Price, \$3. Pp. 256, with illustrations. Philadelphia, 1934.

The original edition of this book was the work of those concerned with the teaching of student nurses in the Philadelphia General Hospital. It was originally intended for the use of those connected with school, but because of its excellent organization and valuable data the book proved useful in other training schools. The present revised edition has been organized to meet requirements of increased ward instruction. The drawings of the various trays to be set up help the student to visualize her work. The material is clearly and concisely presented and, while it is specifically adapted for students of the Philadelphia General Hospital School of Nursing, it should prove a valuable book in any nurses' training school library.

Die Zuckerkrankheit: Leitfaden für Studierende und Ärzte. Von Ferdinand Bertram, leitender Arzt der II. medizinischen Abteilung des allgemeinen Krankenhauses Barmbeck, Hamburg. Boards. Price, 5.80 marks. Pp. 94, with 15 illustrations. Leipzig: Georg Thieme, 1934.

This is written in the best traditional German style, concise, readable, suggestive. Keen observation and an intimate knowledge of the German literature are apparent throughout, although no mention is made of Magnus Levy's epoch-making work on diabetic coma and his demonstration of the low excretion of sodium chloride, or to Umber's (Grote's?) patients who showed over 50 per cent heredity. References to non-Germans are scanty, and German references alone are included in the monographs cited at the end of the volume.

Diabetes is defined as a chronic disease of the entire neuro-endocrine apparatus in which a lowered function of the pancreas stands in the foreground. Lack of insulin leads to inability to burn carbohydrate sufficiently and build it up anew into reserve material. Liver glycogen stands in the center of the problem of diabetes; when exhaustion of the glycogen reserve occurs, the combustion of fat suffers, leading to acidosis, which, according to Bertram's conception, is decisive for the fate of the diabetic patient. A glycogen-free liver can result from untreated diabetes or hypoglycemia and therefore is present during an insulin reaction, at which time acidosis is said to appear, although the latter statement is not supported with sufficient data. He ascribes the complications of diabetes to acidosis rather than to hyperglycemia and explains these first by impairment of the action of insulin due to lowering of the alkalinity of the blood, and secondly, because acidosis exerts a harmful action on cell function, as shown by a diminished formation of antibodies. Although fully realizing the usefulness of glycogen in the liver, the author overlooks its undoubted usefulness in the skin and the probability that its replacement there by dextrose has much to do with the dermatologic complications of the disease.

Bertram's conception of traumatic diabetes is sound and he requires as a *sine qua non* an injury to the pancreas in a proved nondiabetic patient; but he demands also a nondiabetic heredity, which seems hardly justifiable, because, just as obesity and occasionally an infection can arouse a dormant diabetic state, so too might an injury to the pancreas.

Treatment likewise is orthodox, based on an accurate diet to be scrupulously followed even though insulin is added. The carbohydrate in his diet follows a middle course. No sympathy is shown for Stolte's free feeding, particularly with adults. Bertram seldom gives more than the equivalent of 8 bread units each weighing 20 Gm. (12 Gm. of carbohydrate) with 5 per cent vegetables, making a total of from 90 to 120 Gm. of carbohydrate. Fruits are favored because of their content of vitamins, alkalis and levulose. Protein is prescribed in moderate quantities. At the beginning of treatment the fat and also calories in the diet are low and the carbohydrate relatively high not only to guard against acidosis but also because a diabetic patient should never be overfed, since it is not a matter of indifference to the pancreas whether it lives with a body of 60 or of 90 Kg.—a neat adoption of Allen's teaching, although no appreciation is evident of Du Bois and Richardson's demonstration that a low diet may be a high fat diet and that it is the total calories burned, not fed, which count.

Success in treatment is best measured by the patient's subjective feeling of good health and in second degree by the permanent retention of an adequate glycogen reserve rather than by the state of the blood and urine. A sugar free urine and a normal blood sugar are not considered necessary, or perhaps desirable, on the basis that a high blood sugar in diabetes may act as a compensatory offset to the loss of power of utilization of sugar by the tissues, thus enabling the cells of the body to store and utilize glycogen more easily. Shades of Naunyn! Somehow he does not quite catch the point that the diabetic patient who feels better on a free diet, like the man who takes a drink, may be helped only temporarily and that it is really possible for the diabetic patient whose blood sugar is normal, just like the man who does not drink, to maintain perfect health.

Pathology is dismissed with four short paragraphs in fine print, and diabetes in childhood occupies one page. Diabetic

retinitis is an entity and with prolonged treatment may improve. Operations for gallstones are advisable as prophylaxis against diabetes.

Classification is based on the relation of carbohydrate tolerance to ketone bodies. The person with mild diabetes is continuously free from ketone bodies on an adequate caloric diet containing at least 100 Gm. of carbohydrate; the patient with moderately severe diabetes is likewise ketone free on such a diet with the use of insulin; but the patient with severe diabetes is not ketone free on such a diet even with insulin. Obviously Americans would not subscribe to that classification. In a brief paragraph the author beautifully summarizes the somewhat complicated and confused types of sthenic and asthenic diabetes.

According to Bertram, insulin should be given only when prolonged dietetic treatment fails, in contradistinction to the American idea that not until the disease is arrested should one attempt to do without it. Another fundamental difference between Bertram's treatment and American treatment is that he forbids the examination of the urine by the patient under all circumstances. As the number of his diabetic children increases, it is probable that he will revise his attitude in both cases. What would our thousands of diabetic children do, wandering all over the United States for school and work, if they did not know how to examine their urine and guide their own treatment? Rightly the author counsels against making neurasthenics of diabetic patients. He centers his treatment on acidosis, but in America it is a *sine qua non* at the outset of treatment to teach patients that acidosis and diphtheria are similar and that it is a disgrace for a person with diabetes to have either one or the other. Had American doctors only the problem of preventing acidosis, the treatment of diabetes would be simple. Today treatment should strive for the preservation of the health of the patient after he has had the disease ten, fifteen and twenty years or more, because the latter period is the probable duration of diabetes for the average patient who contracts it in the year 1934.

Valuable is Bertram's pointing out that, if too great doses of insulin are given, serious harm can result either by a rapid fall of the blood sugar or by the inducement of too strong a counter regulation, especially manifested by an increased discharge of epinephrine with the consequent rise in blood sugar, impoverishment of glycogen and increase of acidosis. This increased discharge of epinephrine is measurable clinically by a rise in blood pressure and the appearance of a lymphocytosis reaching 60 per cent. The experiments of von Holm are cited in which a continuous weak infusion of insulin was injected into an animal and shown to be far more efficacious than when given in a single dose. Thus, reckoned in terms of a diabetic patient of 60 Kg. body weight with assumed complete loss of endogenous insulin, 7.8 units would keep the urine sugar free fasting, and 48 units if the total caloric needs are wholly replaced by dextrose. He favors doing without insulin if in any way possible and then proves that exactly the opposite course should be followed, by reporting wonderful results with insulin in two patients who obviously needed it months and even years before.

The treatment of coma is sound and he has treated more than 200 cases. He employs intravenous injections of dextrose freely, from 1 to 3 Gm. per unit. In America there is a difference of opinion on this point, but all schools agree that dextrose should be given to a patient with diabetes if he has been without food twelve hours, just as surgeons administer dextrose to persons who do not have diabetes. Insulin is recommended in half hourly doses, from 20 to 50 units, seldom more, and in severe cases intravenously as well as subcutaneously; the early doses should be the larger. Highly concentrated 50 per cent solutions of dextrose are employed in preference to weaker strength, as he wishes to guard against cardiac collapse. Subcutaneously 4.6 per cent dextrose solution is employed and also salt solution. He fully appreciates the advantage of 10 per cent salt solution when uremia threatens through deficiency in salt. As for alkali therapy, the maximum dose is 20 Gm. of sodium bicarbonate and this only when the carbon dioxide is extremely low; even then it should be cautiously and slowly injected because of the oft appearing necrosis that it may entail.

For the circulation he utilizes drugs many of which will sound bizarre to American readers, sympatol, cardiazol, coramin, caffeine, strychnine and hexaton. Because of the disturbed circulation following coma he prescribes from eight to ten days' absolute rest in bed, advice rarely necessary with American methods of treatment. The frequency of urobilinogen in coma is recorded.

Infection is the complication most to be feared, because of the injury to the pancreas through toxins, through reduction of insulin activity due to the accompanying acidosis, and, third, by tryptic ferments found in the leukocytes. The seriousness of an infection in the patient with diabetes he explains by the lowered vitality of the body and its diminished power for antibody formation, made evident by hyperglycemia and acidosis.

The danger of tuberculosis in diabetic patients is fully appreciated, particularly as a sequel to coma, but contrary to American experience he has seldom encountered severe acidosis in tuberculosis.

Coma is classified into three types, the typical Kussmaul dyspneic coma, cardiovascular coma and renal coma, although he recognizes that the types intermingle. Many will disagree with Bertram that coma sometimes develops without recognizable causes or that it develops in the course of one or two hours or even a shorter period. The unreliability of dependence on laboratory tests for the prognosis in coma is rightly emphasized, as also the importance of the blood pressure and its treatment. Despite his use of dextrose, Bertram records five cases in which hypoglycemic collapse following coma led to sudden failure of the circulation. This is what surgeons fear when dextrose is given to patients with diabetes. These facts show that the more frequent use of micro blood sugar tests should be made, because they would avert such catastrophes. To give dextrose to offset the danger of insulin and then to rely only on tests of the urine is almost like jumping from the frying pan into the fire.

Bertram holds that, even if of moderate degree, diabetes is an absolute indication for interrupting pregnancy and at the same time for sterilization to protect the mother and to stop hereditary transmission. Diabetic patients desiring marriage should be registered at the heredity bureau. Would our 400,000 living diabetic patients and their 800,000 brothers and sisters who also carry the disease take kindly to registration, leaving to officials to decide whether they should marry? An experiment on a national scale to interrupt all diabetic pregnancies and sterilize all diabetic patients is unique, and the rest of the world will watch it with interest; but it is a question whether France will care to adopt it and thus run the risk of losing another Clemenceau and another Joffre, whose diabetes even without insulin did not appear to be a great handicap to their careers, or whether we would wish to miss the chance of losing another Edison or the discoverer of the cure of one of the three diseases for which this century is famed.

The book is instructive and stimulating and it is delightful to have an author leave the beaten path and force the reader to reconsider his own "principles of action and to give the reasons for the same in each case."

A Compend of Diseases of the Skin. By Jay Frank Schamberg, A.B., M.D., Professor of Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania, and Carroll S. Wright, B.S., M.D., Professor of Dermatology and Syphilology, Temple University School of Medicine. Ninth edition. Cloth. Price, \$2. Pp. 331, with 129 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1934.

The ninth edition of this compend has been revised and enlarged, and it "is designed for the use of practitioners and students, as a rapid reference work and key to the study of dermatology." The common skin conditions are succinctly described, and there are excellent tables detailing the differential diagnosis of the more important skin conditions that are easily confused clinically. The treatment of the more important conditions is briefly but clearly discussed. The article on syphilis is excellent, and the concise discussion on treatment is unusually complete when one considers its brevity. The work serves a useful function as an outline of study for the student but must be supplemented by the larger dermatologic textbooks for more detailed discussion of the subject. Figure 67 (p. 181), labeled chloasma, is more probably one of vitiligo. Figure 101 (p. 237) should more properly be labeled maculopapular syphilis. In

the article dealing with x-rays, on page 311, the old MacKee formula is given instead of that given in his latest textbook. In the preface to this edition, comment is made that "material on lymphogranulomatosis cutis, a relatively new disease, has been introduced," when lymphogranuloma inguinale is meant.

Œuvre scientifique de J. Babinski. Recueil des principaux travaux publiés par les soins de J. A. Barré et al. Paper. Price, 180 francs. Pp. 638, with 69 illustrations. Paris: Masson & Cie, 1934.

During the fifty years from 1882 to 1932 Babinski alone and in collaboration with his pupils published 288 articles, which are listed at the end of this volume. Seventy-nine articles, arranged in eleven groups, have been selected for reproduction. Among them are those dealing with the discovery of the Babinski sign and Babinski's conception of hysteria and hypnotism. Almost every aspect of clinical neurology is covered, and the volume gives in convenient form not only the chief works of this master but a clear view of the progress of neurology in the most eventful fifty years of this department of medicine.

The Spastic Child: A Record of Successfully Achieved Muscle Control in Little's Disease. By Marguerite K. Fischel. Cloth. Price, \$1.50. Pp. 97, with illustrations. St. Louis: C. V. Mosby Company, 1934.

This monograph is a unique and valuable contribution to medical literature. While the book is a written record of a mother's attempt to teach muscle control to her child with Little's disease, it is replete with medical as well as human interest. The methods and accessory aspects of treatment are described in simple and accurate language. Valuable points are intimately discussed which should serve a most useful purpose to those faced with similar problems. The presentation is concise, and yet the medical reader will be impressed with a wealth of valuable data that this record contains. The book will serve as a valuable document of what can be accomplished with a handicapped child by an ingenious and persevering mother.

Manual de medicina clinico y de laboratorio. Por el Dr. C. M. Desvergne y Galdos, de las Facultades de New York, Paris y Madrid. Paper. Pp. 568. Habana: Cultural, S. A., 1933.

This large volume is a glossary of medical terms and differs from the usual dictionary in that the definitions are more lengthy and descriptive. The medical words are classified into groups comprising medical diseases, medical phenomena, signs, reflexes, syndromes, and laboratory and surgical procedures. The authors use the proper names of the various terms in the great majority of instances and list these in alphabetical order in their respective groups. The book is divided into ten parts. The first part, which constitutes almost half of the volume, is a glossary of medical diseases. The remaining nine parts list the various phenomena, syndromes, signs, and so on, in a fashion similar to the first portion.

The Care and Feeding of Children: A Catechism for the Use of Mothers and Children's Nurses. By L. Emmett Holt, Jr., M.D., Associate Pediatrician to the Johns Hopkins Hospital, Baltimore, Md. Fifteenth edition. Cloth. Price, \$1.25. Pp. 259. New York & London: D. Appleton-Century Company, Incorporated, 1934.

This little volume has been a standard guide in the care and feeding of children for more than thirty years. Its popularity is well merited, for it is carefully organized to meet the little daily problems that arise with the inexperienced mother. The present revision brings the book down to date with enlightened medical opinion. For a concise textbook considering the care and needs of the well child, this volume has no equal.

A Suggestive Budget for Families of Low Income. Prepared by the Budget Committee of the Family Welfare Committee and the Housing Committee of the Washington Council of Social Agencies. Paper. Price, 35 cents. Pp. 46. Washington, D. C., 1934.

This is issued to offer a guide for relief workers in estimating individual or family needs. It is detailed as to items of diet for persons under various circumstances. Housing and clothing needs are also itemized. In the summary, the total estimated amount needed for "the basic needs of families of low income permitting a limited choice as to quality" is \$1,921.14. A second budget "provides only for the basic needs of families of low income" and is estimated at \$1,291.40.

Fuss und Bein: Ihre Erkrankungen und deren Behandlung. Ein Lehrbuch. Von Prof. Dr. med. Georg Holmann, Direktor der Orthopädischen Universitäts-Klinik, Frankfurt a. M. Second edition. Paper. Price, 24 marks. Pp. 380, with 326 illustrations. Munich: J. F. Bergmann, 1934.

This combines the well known works of the author on the foot and the leg. The monograph is complete, including deformities and disabilities of the foot and the leg, all of which are described and illustrated by line drawings, roentgenograms and operative technic. The book that can be recommended to all surgeons who read German.

Medicolegal

Dental Practice Acts: Filing of Charges Condition Precedent to Revocation Proceedings.—The Illinois Department of Registration and Education, without any formal charges having been first filed with it, instituted revocation proceedings against Kalman, Niedermeyer and another, all licensed dentists employed by the Chicago Dentists. The department served notice on each of the dentists that on a stated day it would investigate his actions to determine whether or not he had obtained money by false or fraudulent representations or had been guilty of dishonorable conduct or of certain other unprofessional acts. The three dentists then filed a bill in the superior court, Cook County, to enjoin the department and its dental committee from proceeding further in the matter. The court sustained a demurrer interposed by the defendants and dismissed the bill, whereupon Niedermeyer appealed to the Supreme Court of Illinois.

The Illinois Civil Administrative Code, as amended, defines the procedure to be followed in revoking a license to practice dentistry, as also does the Illinois dental practice act. The Civil Administrative Code provides that the department "may upon its own motion and shall upon the verified complaint in writing of any person" initiate revocation proceedings. On the other hand, the dental practice act, prior to February 1933, provided, in part, as follows:

The board [meaning the Department of Registration], when written charges have been filed with its secretary, and seem sustained by proof, shall fix a time and place for the examination of a person so charged and shall give written notice to the said person of the time and place and furnish him with a copy of the charges. . . .

For the reasons stated in *Schireson v. Walsh*, 187 N. E. 921 (THE JOURNAL, Aug. 4, 1934, p. 367) the Supreme Court held sections 60(a)—60(1) of the Civil Administrative Code unconstitutional as applied to dental practitioners. The department, the court held, in proceedings to revoke a license to practice dentistry, must follow the procedure laid down in the dental practice act as it existed at the time of the alleged professional misconduct on the part of Niedermeyer, namely, prior to February 1933.

The right to practice dentistry, said the Supreme Court, is a valuable right, a property right within the due process of law clause of the constitution. Revocation of a license to practice dentistry not only carries with it disgrace and humiliation but deprives the licensee of his means of earning his livelihood. In a proceeding of this nature due process of law requires a definite charge, adequate notice and a full, fair and impartial hearing. While it is not necessary that charges of professional misconduct should be drawn with the same accuracy and certainty as an indictment or information in a criminal case or with the refinements of pleadings in courts of record, yet such charges should be so drawn as to bring the alleged act of misconduct clearly within the purview of the statute and should specify the time and place when and where such prohibited act was committed. The right to proper notice and a sufficient and explicit charge is not procedural but substantive. The supposed charge in this record shows that the contemplated hearing was a hearing in the nature of an inquisition similar to an investigation by a grand jury. This is not the hearing that is provided by the statute. Neither the dental committee nor the department has the power, under the statute, to originate or prefer charges against a dental practitioner. The charges against Niedermeyer, in order to confer

jurisdiction on the dental committee or the department, should have been in writing, filed with the secretary of the committee, and should have contained direct, positive and specific allegations based on the alleged commission by Niedermeyer of some of the acts prohibited by the dental practice act. Under the notice purporting to contain the charges against Niedermeyer and served on him by the department, concluded the court, neither the department nor its dental committee had jurisdiction to conduct the alleged investigation against him or to enter any order revoking or suspending his license.

The Supreme Court, therefore, directed the superior court to overrule the demurrer to the bill.—*Kalman v. Walsh* (Ill.), 189 N. E. 315.

Charitable Hospitals: Liability for Neglect in Selecting Employees.—The appellee, a pay patient in the appellant hospital, a charitable institution, was injured by reason of the negligence of a hospital nurse in giving the patient a vaginal douche. The trial court gave judgment for the appellee and the hospital appealed to the Supreme Court of Appeals of Virginia.

The liability of a charitable hospital for negligent acts of its servants, said the Supreme Court of Appeals, was settled in Virginia in the case of *Weston's Adm'x v. Hospital of St. Vincent, etc.*, 131 Va. 587, 107 S. E. 785, 23 A. L. R. 907. In that case, the court held that the only duty which a charitable hospital owed to its patients was the exercise of due care in the selection and retention of its servants. In the present case, continued the court, there was no question that the jury was justified in concluding that the negligence of the nurse was the proximate cause of the patient's injuries. The superintendent of nurses testified that, in selecting a nurse, one of the requirements was that the applicant should have had three years of high school work. The evidence showed that the nurse responsible for the patient's injuries had never attended high school and that she had attained only the tenth grade in a graded school situated in a small town. During the three years that she had been in the hospital, she had been repeatedly reprimanded for infractions of the rules of the hospital, had been threatened with dismissal and had been retained only because the superintendent felt sorry for her. It is not sufficient to say, said the Supreme Court of Appeals, that a nurse is competent simply because she is capable of discharging the manual duties incumbent on her as a nurse. It is a matter of common knowledge that the welfare of a patient is as much the responsibility of the nurse as it is of the physician. If the nurse is lacking in educational preparation, if she is guilty of indiscretions that impair her physical or mental status, if she is lacking in that moral character which imbues the patient with confidence, then it cannot be said that she is a competent person to be placed in charge of a helpless patient.

The finding of the trial court that the hospital was negligent in the selection and retention of the nurse was amply justified by the evidence, concluded the court, and the judgment against the hospital was affirmed.—*Norfolk Protestant Hospital v. Plunkett* (Va.), 173 S. E. 363.

COMING MEETINGS

- American Society of Tropical Medicine, San Antonio, Texas, November 14-16. Dr. Henry E. Meleney, Vanderbilt University School of Medicine, Nashville, Tenn., Secretary.
- Inter-State Postgraduate Medical Association of North America, Philadelphia, November 5-9. Dr. W. B. Peck, 27 East Stephenson Street, Freeport, Ill., Managing-Director.
- Pacific Coast Society of Obstetrics and Gynecology, Oakland and Del Monte, Calif., November 21-23. Dr. Clarence A. De Fuy, 230 Grand Avenue, Oakland, Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 14-16. Dr. Julio R. Rolenson, Box 3403, Santurce, Secretary.
- Radiological Society of North America, Memphis, Tenn., December 3-7. Dr. Donald S. Childs, 607 Medical Arts Building, Syracuse, N. Y., Secretary.
- Southern Medical Association, San Antonio, Texas, November 13-16. Mr. C. P. Loran, Empire Building, Birmingham, Ala., Secretary.
- Southern Surgical Association, Sea Island, Ga., Dec. 11-13. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
- Western Surgical Association, St. Louis, December 7-8. Dr. Albert H. Montgomery, 122 South Michigan Boulevard, Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- *One Hour Two-Dose Dextrose Tolerance Test. W. G. Exton and A. R. Rose, Newark, N. J.—p. 381.
Some Medicolegal Aspects of Iso-Agglutinins. H. A. Heise, Milwaukee.—p. 400.
Preparation of Neurologic Material for Histologic Study. J. W. Kernohan, Rochester, Minn.—p. 410.
Further Studies in Antigen Emulsion Preparation for Ball Test for Syphilis. B. S. Kline, Cleveland.—p. 426.
Cyanide Poisoning. A. O. Gettler and A. V. St. George, New York.—p. 429.
Treatment of Malignant Neutropenia by Injection of Liver Extract. W. B. Martin, Norfolk, Va.—p. 438.

One Hour Two-Dose Dextrose Tolerance Test.—Exton and Rose perform the one hour two-dose dextrose tolerance test by dissolving 100 Gm. of dextrose in about 650 cc. of water. This solution is flavored with lemon and divided into two equal doses, which are served cold. Three containers with preservative against glycolysis are kept at hand for the blood specimens and three containers for the urine specimens. When collecting the specimens the subjects should empty the bladder as completely as possible. The following steps are taken after a fast, preferably over night: 1. The samples of blood and urine are collected and the first dose of dextrose is given, from one to two minutes being allowed for its ingestion. 2. Thirty minutes after the ingestion of the dextrose the blood sample is collected and the second dose of dextrose is given, from one to two minutes being allowed for its ingestion. Thirty minutes later, samples of blood and urine are collected. The third urine container is given the subject for a sample of the urine next voided whenever a (post) sample is desired. When the results of the foregoing procedure are plotted, the interpretation of the first part of the curve, that is, the part that includes the original and the thirty minute samples, is exactly the same as the interpretation of the same part of the curve of the older procedure, and the same deductions are drawn accordingly from the blood and urine sugar values. Interpreting results of the second part of the one hour two-dose tests indicates that normal subjects respond to the second dose of dextrose with a greater fall in blood sugar than that occurring during the same period after only a single dose and there is no sugar in the urine. The criteria for determining diabetes in the one hour two-dose test are a more or less steep rise of not less than 10 mg. of blood sugar in the sixty minute sample following the second dose of dextrose and the relation of blood and urine sugar values to the severity of the disease. The criteria of the test for renal glycosuria are: blood sugars that follow the normal course, or in any event never reach the diabetic level, and sugar in both urine specimens. The criteria of alimentary glycosuria are: a sugar-free urine after fasting with sugar in the final urine and blood sugars that follow the normal curve even when the level is higher than normal. Up to the present time the authors have not encountered a single instance in

which the new test disagreed with the older when the results of the older test were satisfactory. On the other hand, many cases gave doubtful or misleading responses to the older test when results of the new test were consistent and specific.

Acute Fractures of Os Calcis.—In fractures of the os calcis following the reduction of the swelling, Forrester performs a subcutaneous tenotomy of the achilles tendon, using the zigzag method and taking all pull of the muscle off the distal displaced fragment. Direct traction is used to pull this posteriorly displaced fragment down as near normal as possible, restoring the original longitudinal arch. The lateral deformities below the malleoli are corrected by utilizing the method devised by Bohler, to which the author has added his knee pressure splint, using the buttons devised by Bohler, and, using them on the same splint, he is enabled to reduce forcibly the bony deformity below the malleoli. After the reduction is made, it is maintained by manual pressure pulling the heel down at the same time. At this point the plantar position of the foot is also maintained by keeping the ball of the great toe in plantar flexion instead of inversion. A stockinet is then applied from the toes up to the knee. A posterior plaster mold is then applied followed by a circular skin-fitting plaster cast in which a walking iron is incorporated. No weight bearing is allowed for the first twenty-four hours or until the plaster has hardened. After that the patients are instructed to walk on the cast without any other assistance and to move the toes frequently each day to prevent any edema. This type of cast is maintained for at least two months. At the end of that time an elastic stocking or an Unna boot is employed for about sixty days, and in the meantime the patient is given education of all leg muscles, together with foot exercises and the ultimate use of the shoe worn previous to the accident. A review of his results in 150 cases indicates that a combination of the author's type of treatment with Böhrer's ambulatory cast and walking iron results in a material reduction not only

in temporary disability, which usually runs from a year to a year and a half, but also in the specific loss, which runs from 60 to at least 80 per cent.

Reduction of Compression Fractures of Vertebral Bodies.—Parnley presents a method for the reduction of compression fractures of the thoracic and lumbar vertebrae, together with an improved method of constructing a plaster shell to maintain the corrected position. The patient is anesthetized, and if the fracture is located in the twelfth dorsal or in the first, second, third or fourth lumbar vertebra hyperextension can be obtained best by swinging the patient between two tables, face down, one table beneath his chest and the other beneath the upper third part of his thighs. If the fracture is above the twelfth dorsal vertebra the position is the same except that the table or elevation under the chest is moved upward, toward the shoulders, the neck also being hyperextended by means of elevation or suspension of the head, and that the second table is placed under the hips or pelvis. The elevation of the hips or pelvis should be considerably higher than that of the shoulders. Then a piece of felt is cut to fit the patient's back. This felt should extend from well over the shoulders to about the level of the greater trochanters and to the anterior axillary line on each side. If palpation over the injured vertebra reveals a slight "hump" or prominence, a sand bag about 2 inches thick and about 4 inches broad is placed directly over the injured vertebra and the bag is struck several times with quick sharp blows from the flat surface of a hammer weighing from 2 to 4 pounds. This should be kept up until the "hump" disappears or until it is obvious that there is an impaction of such a degree that it is deemed impossible to break it up. When the reduction is completed, the posterior felt jacket is fitted to the patient and held in position by adhesive plaster. Then, with 6 inch widths, beginning well over the shoulders, plaster bandage is laid transversely. It should be laid smoothly and each fold should go well beyond the margin of the felt. Then the plaster must be rubbed and smoothed to fit every depression and every prominence of the patient's back as perceived through the felt. After this first layer begins to set, others are added longitudinally and obliquely in both directions and again transversely to the number of from twelve to fifteen. When the shell is made, it is allowed to remain on the patient for a few minutes until it hardens. Before the shell becomes hard, it is trimmed to conform to the size of the felt. When the shell has dried thoroughly, a piece of stockinet is stretched over the inner side and held with adhesive plaster, and the patient is placed in the cast. During the time required for the plaster to dry, the patient is kept in bed in the hyperflexed position with Buck's extension in force. He is given one-fourth grain (0.016 Gm.) of morphine sulphate or one-third grain (0.022 Gm.) of pantopon hypodermically every four to six hours to control intestinal peristalsis and muscular contractions. The patient is kept in the shell for a week, not being allowed to turn over or move about. When placed in the shell, he is allowed to flex his knees as he desires. The patient may return home any time after he has been placed in the cast.

Pyelographic Injection of Perirenal Lymphatics.—Abeshouse believes that the phenomenon of pyelolymphatic backflow can be graphically demonstrated by injection of the renal and perirenal lymphatic canals during pyelography. Injection of the renal and perirenal lymphatic canals during pyelography occurs not only in patients with parasitic or non-parasitic chyluria but also in patients with an absence of chyluria or a nondemonstrable chyluria. The author is of the opinion that injection of these lymphatic canals is the result of the easy penetration of the pyelographic medium into anomalous renal lymphatic canals, which may be congenital or acquired. The acquired type of anomalous renal lymphatics, which is usually associated with a chyluria, is exemplified by the dilatation and tortuosity of the renal lymph vessels following an obstruction of the thoracic duct resulting from an inflammatory, suppurative or neoplastic disease in the thoracic, mediastinal, peritoneal or retroperitoneal region. The chyluria is the result of the rupture of one or more of these dilated, tortuous lymph vessels, thus establishing a communication between the renal lymphatics and the pelvis. It is through

the same points of rupture that the contrast fluid penetrates and injects the renal and perirenal lymphatics. The congenital type of anomalous renal lymphatics in all probability is present in the cases of injected perirenal lymphatics unassociated with a demonstrable chyluria and in some of the cases of nonparasitic chyluria. In this type, anatomic variations in the course and structure of renal lymphatics may be present and produce a direct communication between the renal lymphatics and the pelvis which will permit the easy penetration of the pyelographic fluid. Overdistention of the renal pelvis and excessive pressure at the time of pyelography play no part in the production of injected renal or perirenal lymphatics. The author bases the foregoing remarks on a study of eleven cases of injected perirenal lymphatics from the literature and two personally observed cases unassociated with a demonstrable chyluria.

Operation for Maldescended Testicle.—To overcome the disadvantages and provide greater postoperative comfort and a shorter period of disability from the Torek operation, Wolfson and Turkeltaub have modified the technic as follows: Over the inguinal canal, hockey-stick shaped incisions, beginning at the pubic area, are made through the skin and the aponeurosis of the external oblique muscle. The broken lines are directed outward and upward. The external abdominal ring is split through at the middle of the intercolumnar fibers. The blades of the aponeurosis are separated widely to permit more mobility and better relaxation of the arched fibers of the internal oblique and transversalis muscle. The gubernaculum testis should be identified and traced to the lower attachment, which is then doubly clamped low down, cut and tied at both ends. The testicle is palpated, viewed, appraised and its relationship studied, and it is lifted if it is covered with a veil of cremasteric muscle. The testicle and the spermatic cord are withdrawn gradually from the inguinal canal. A finger dissection will mobilize this structure from its bindings of cremasteric muscle, adhesions and transversalis fascia, performed by starting posteriorly and working deeply and high up into the retroperitoneal space. Anteriorly and laterally, a similar performance liberates the spermatic cord and the vaginal process from the anterior and lateral walls. The vaginal process or peritoneal tube is freed from the vas deferens and spermatic vessels of the cord. The cord may be lengthened by separating all peritoneal remnants and adventitious tissue between the vas deferens and the spermatic vessels as far down as the testicle and epididymis. If additional length is required, a complete and high dissection of the posterior parietal peritoneum from the spermatic vessels up to the renal area will accomplish the purpose. The new bed for the testicle is prepared by forcing a finger to the bottom of the scrotum. The base of the scrotum is next grasped with two Allis forceps 2 cm. apart. A transverse slit is made through the skin and dartos between the clamps. Another incision, equal in length, parallel but lower, is made on the inner and upper part of the thigh, facing the scrotum. The cord structures are aligned correctly. If the length and the position of the testicle in the scrotum are satisfactory, a clamp is passed through the scrotal incision to grasp and withdraw the free end of the gubernaculum testis through the scrotal slit. The testicle is carried to the bottom of the scrotum. A union of the upper skin flap in the thigh to the posterior skin flap of the scrotum is then established with interrupted sutures. The gubernaculum is stitched to the newly formed posterior skin suture line with interrupted fine silk sutures. The skin wound is closed with silk sutures, which also incorporate the gubernaculum to this union. The inguinal canal and structure are reformed and reunited with number 1 catgut sutures. The spermatic cord should not be displaced. Two weeks after the orchiopexy the patient is to resume his physical activities. Two months later the scrotum is detached from the thigh, by incision round the circumference of the scar and through the gubernaculum. A few interrupted sutures close the wounds of the two surfaces. The authors performed this operation with satisfactory results in forty-five cases of maldescended testicle.

Autogenous Milk Vaccine Therapy in Treatment of Peritonitis.—Anderson has been using autogenous milk vaccines in the treatment of peritonitis since 1929. Immediately preceding any abdominal operation, five numbered Erlenmeyer

flasks, each containing 30 cc. of milk, are boiled and sterilized for thirty minutes in an electrical sterilizer and then allowed to cool. A thin skin forming on the surface of the milk is removed with a sterile platinum loop. The sterile flasks are then set aside. If, when the abdomen is opened, a local or general peritonitis is present, cultures are obtained with a sterile spoon or platinum loop. If there is much peritoneal fluid present, about 4 drachms (15 cc.) of the fluid is used to inoculate the milk in each flask. Cultures can also be obtained by dipping the blind end of the appendix after removal into the sterile milk. These flasks are then corked and placed in an incubator at 37.5 C. At the end of twelve hours, flask 1 is removed from the incubator and sterilized by boiling over a direct gas flame for five minutes. If a curd forms either before or after boiling, it is removed by filtering through sterile cotton and the filtrate is used for injection. Flasks 2, 3, 4 and 5 with milk cultures are removed in twenty-four, thirty-six, forty-eight and sixty hours, respectively, treated and injected if deemed necessary as described for flask 1. All milk cultures are killed by heat at the end of an incubation period of four days, as it is the author's opinion that maximal growth has been obtained by that time. Chemical changes occur which retard the growth of the bacteria, and undesirable products of fermentation may result. The filtrates of these four-day cultures are kept in sterile sealed bottles on ice for future use if necessary. Injections are given intramuscularly in the gluteal region. The vaccine material should not be injected directly into the blood stream. If any anaphylactic signs or symptoms appear, 0.6 cc. of epinephrine hydrochloride should be given. The amount of vaccine injected should be determined by the condition of the patient; from 10 to 25 cc. has been employed, usually 15 cc. or more. Two or three injections have been given as a rule. In the author's eighteen cases of appendicitis with localized or generalized peritonitis treated by this method there was only one death. In the seventeen patients who recovered, drainage was observed to be much less than usual in such cases, and recovery was more rapid. The patient who died had had acute pain in the lower right quadrant for five days before coming to the hospital, and at operation an extensive peritonitis with a great deal of free pus was found.

Congenital Urinary Anomalies.—Wiseman states that before surgery for the obstructive effects of a congenital anomalous formation of the urinary tract is undertaken it is important to determine beforehand (1) the presence or absence and the degree of infection in the kidney on which it is proposed to carry out a plastic procedure, (2) the functional status of the involved organ and (3) the possibility of bilateral involvement. If the hydronephrotic kidney is a functionless mass and its mate can be demonstrated to have been spared a similar fate and to possess adequate functional capacity, nephrectomy should be performed. The existence of demonstrable bilateral hydronephrosis or pyelectasis of a solitary kidney are indications for conservative surgical procedures. The existence of a congenital urinary anomaly, by itself, is a potential source of obstruction and subsequent urinary stasis and infection. Anomalous blood vessels in close proximity to the upper third of the ureter, although not actually responsible for the collapse of the ureter, may by their pulsations interfere with the normal flow of the peristaltic wave down the ureter and thereby promote stasis and pyelectasis. Heminephrectomy of an infected hydronephrotic pelvis may be required when a solitary kidney is supplied with a double pelvis and corresponding ureteral reduplication, one of which becomes affected. This procedure may be employed for the resection of a unilateral fused kidney. Nephropexy, preferably by the Kelly method, may facilitate pelvic drainage and obviate further ureteral angulation, whenever the hydronephrotic kidney displays a tendency toward undue or excessive mobility. A ureterocele or ureterovesical cyst is usually associated with pronounced narrowing of the ureteral orifice which contributes to urinary stagnation and the development of pyelectasis of varying degree on the involved side. The accepted surgical procedure for their correction may be by the suprapubic approach with resection of the prolapsed cystic sac or transurethral electrodesiccation, the latter being preferred. Surgery in unilateral fused kidney is contraindicated unless complications such as calculus, pyonephrosis or hydronephrosis develop, in which case pyelotomy or heminephrectomy may be required. The measure of success or failure for the correction of hydronephrosis and the contributory ureteral obstruction may be gaged by the alleviation of symptoms, the pyelographic evidence of decreasing capacity of the sac and the return of its functional capacity estimated by differential functional renal tests, and less accurately by the density of dye excreted following intravenous excretion urography.

Preoperative Roentgen Treatment in Renal Tumors.—Randall believes that the embryonic character of renal tumor in childhood permits one to expect a marked diminution in the size of the mass from adequate roentgen therapy. Such irradiation cannot be expected to be completely curative, i. e., to destroy completely all neoplastic cells. Recurrences after irradiation exhibit increased resistance to this form of therapy and ultimately the new growth exceeds irradiative destruction, i. e., becomes "fast" to any type of irradiation. The late arrival of these cases to the consultant surgeon, owing to their latent symptoms, renders their operative removal both hazardous and at times impossible. Preoperative irradiation not only decreases this operative hazard but by the decrease in size minimizes the additional danger of manipulative and traumatic spread of malignant cells. The choice of time for operation, after the completion of thorough irradiation, appears to be between the fourth and the sixth week. There has been no detrimental effect to prompt healing when operating at this interval after irradiation. The leukocyte count during the course of treatment should be watched as some patients develop a leukopenia, which is evidence of lowered resistance and, if marked, would contraindicate further irradiation at that time. The preoperative irradiation should include the chest and the abdomen, producing an infertile field for metastatic transplants that may be dislodged by the handling of the tumor at extirpation. Three cases following this method are reported.

Use of Iodized Oil in Common Duct Obstruction.—Thorlakson and McMillan used iodized poppy-seed oil in visualizing roentgenologically the biliary passages in five cases of obstruction of the common duct after drainage had been established. The roentgenograms illustrate the changes that occur in severe cases during the course of treatment, especially showing the marked improvement in the intrahepatic biliary system which results from prolonged drainage. In the authors' cases the poppy-seed oil passed into the duodenum without delay, but it also ran up into the duct system and outlined the intrahepatic biliary tree, in spite of the fact that there was obviously no distal obstruction. They feel that failure to visualize the intrahepatic system depends on a widespread cholangitis and that this cholangitis subsides following prolonged drainage or drainage and irrigation. The intrahepatic system will be visualized well as soon as the ducts are cleared of the viscid stagnant contents, and thus visualization indicates improvement following drainage and not necessarily obstruction, as Ginsburg and Benjamin point out. The authors' interpretation of the cases showing incomplete visualization of the biliary tract is that the finer radicles are filled with tenacious infected mucus which prevents the oil from spreading freely throughout the smaller bile passages. In such cases irrigation of the ducts with warm physiologic solution of sodium chloride is indicated and if this procedure is carried out with ordinary aseptic precautions it is not attended by any ill effects.

Benign Epithelial Invasion.—Boyd states that the columnar cells lining a tubular gland or covering a glandular surface may proliferate and form new glandular structures, not only on the surface but also in the depths of the tissue, to such an extent that the new formation may be separated widely from the original surface, although connected with it by a narrow tract. Should the latter be tortuous, the original connection with the surface can no longer be recognized in a single section and a mistaken diagnosis of carcinoma may be made. Such a condition may be called benign epithelial invasion. Stratified epithelium is also liable to this change, as may be seen at the edge of a chronic ulcer of the skin or in the lining of the ureter. The columnar epithelium lining the gallbladder, fallopian tubes, uterus and stomach offers excellent examples of the process, which the author discusses.

Human Immunization Against *Pneumococcus*.—Ross states that following ingestion of *pneumococcus* vaccines about 75 per cent of the persons tested formed protective antibodies against type I and about 60 per cent against type II. The results for type III are approximately as for type II. Anti-

bodies for type I have been found in most of the serums examined from seven to fourteen months after the oral administration of the vaccine. The indications are that the duration is the same for the three types. The protective substances appear promptly, being present within from two to three days following six feedings. The number of feedings employed has varied from two to ten. In one instance when two doses were given antibodies were formed. In some cases ten doses elicited no response. A new set of feedings was followed by the appearance of protective substances in the blood of about 50 per cent of such cases. It is estimated that a practical procedure would employ the pneumococci from 1,200 cc. of growth per type on each of six to ten successive days, the bacterial content being estimated at 10^8 per cubic centimeter. The use of completely autolyzed cultures, which contain several times as much antigenic material as the bacteria present in a growth of eighteen hours, would reduce proportionately the volume of broth to be handled. None of the several forms in which the vaccine has been prepared have proved superior to the others. The concentration of antibodies formed is generally such that 1 cc. of serum will protect a mouse against 5,000 fatal doses of pneumococci (types I and II). It is believed that these protective substances indicate a generalized resistance to the pneumococcus. Agglutinins have not been detected in serums in which protective antibodies have been found. Natural protective antibody against type I has been found in fairly large amounts in 10 per cent of the serums examined and in smaller amounts in 20 per cent more; in the case of type II the figures were 41 and 18 per cent; for type III, 31 and 50 per cent.

Effect of Liver on Appetite and Growth.—Johnson and Palmer studied the effect of several meat supplements on the growth and appetite of rats. In the first experiment fresh pork liver, when fed as a 0.5 Gm. daily supplement to a purified diet, increased growth and food consumption as compared to the controls receiving only the basal diet. When food consumption was controlled by use of the paired-feeding method, the rats receiving the liver supplement did not grow significantly faster than the controls. Liver meal, when fed in amounts equivalent to the fresh liver, increased the growth rates of the rats receiving it to a lesser degree than the fresh liver. Beef muscle meal when fed as a supplement to the basal diet did not increase food consumption. This result is

evidence that the palatability of a food itself is not a measure of its ability to stimulate the appetite for other foods with which it is not mixed. In the second experiment the appetizing properties of fresh pork liver, beef liver and calf liver and the effect on growth of fresh beef liver when food intake was controlled were studied. The three kinds of liver were found to increase food consumption and growth to a similar extent. The increased growth, however, is entirely the result of appetite stimulation, as shown by the equal growth of controls and those receiving the beef liver when food intake was equalized. Male rats showed a decidedly greater growth response to fresh liver supplements than did female rats. This was due in part to a greater consumption of food by the male rats and also to the fact that they utilized the greater food intake much more efficiently than the female rats. The experiments confirm the conclusion of Palmer and Kennedy and suggest a different interpretation of the growth resulting than from a so-called growth factor. The factor should be referred to solely as an appetite factor.

Hydatid Disease of the Brain.—Dew discusses hydatid disease of the brain and states that, as in the case of all organs, infestation of the brain with echinococcal disease may be either primary or secondary. In the former the cysts are derived from hexacant embryos which, after passage through the liver and lungs, have been carried by the carotid arterial stream to the brain. Secondary cysts are metastatic and result from the sowing by the blood stream of scolices, derived from a fertile primary simple cyst that has ruptured into the left side of the heart. It is obvious, although the fact has not been universally recognized, that the pathologic and clinical

aspects of the two types are different and, until this is appreciated, much confusion must occur in their interpretation. Primary cysts occur almost exclusively in young children, are simple, and give rise to clinical syndromes similar to any other benign, noninfiltrating tumor and are amenable to surgical operation. Secondary cysts occur almost exclusively in adults or adolescents, produce protean nervous manifestations owing to their multiplicity, and invariably produce fatal results, not being amenable to surgery.

Surgical Limitations in Treatment of Peritonitis.—Buchbinder states that the operative therapy of spreading peritonitis is limited to removal or closure of a septic focus, aspiration of the exudate and closure of the peritoneum without drainage, and that the abdominal wound above the serosa should be drained. The author's experimental and clinical observations are opposed to the opinion that operation during a spreading peritonitis increases the rate of spread and the area of contamination. Postoperative spreading peritonitis, particularly when the source is the intestinal tract, is nearly always a catastrophe, yet there is both justification and indication to invade the operative field early in the event of serious soiling. When a mounting temperature and particularly a rapidly mounting and persistently high pulse are present it is preferable to reopen the abdomen promptly, rather than to wait. It does not require a general peritonitis, or even a widespread lesion, to cause death. Therefore, prompt differentiation between serious soiling with infection and ileus without gross soiling must be made. All methods of direct surgical attack on suppurative spreading peritonitis, based on alteration of or interference with the functions of absorption and exudation, tend to increase the mortality. Drains function in localized peritoneal abscesses, but in spreading processes they not only encapsulate, regardless of the consistence of the exudate, but also provoke residual abscess and increase the diffusion of the infection.

Experimental Endobronchial Occlusion.—In searching for a substance to produce bronchial occlusion, Cutler and Wood recalled that painless strictures of the urethra were not uncommon following irrigations with acriflavine hydrochloride solution, which led them to believe that this drug in greater concentrations might have the desired action on the bronchus. Dogs weighing from 8 to 20 Kg. were used. They were anesthetized by the intraperitoneal injection of sodium pentobarbital. The bronchoscope was pushed down to the position where cicatrization was desired. Acriflavine was applied to the desired bronchus by moistening a cotton swab, wrapped tightly on the end of a long stiff wire, with the solution. The excess solution was expressed and the applicator was placed just within the bronchial orifice for from six to ten minutes, the duration of the application depending on the size of the bronchus. The swab should fit snugly into the orifice of the bronchus. When the swab was removed, if any excess secretion was present, this was wiped dry with a sponge. The treated area was usually a deep scarlet and its mucosa seemed withered. In the case of the lower right lobe, each of the numerous openings were treated in the same manner. If the entire right or left main primary bronchus was to be treated, a cotton wick 0.5 cm. by 5 to 8 cm., from which all excess of acriflavine had been pressed out with a sponge, was passed through the bronchoscope and packed tightly into the main primary bronchus and left in place for from fifteen to twenty minutes. Any excess solution was wiped dry when the wick was removed. By this method the primary bronchus can be occluded completely, two applications usually being necessary. The solution of acriflavine should be made up fresh every day. A fresh cotton applicator should be used for each bronchus. At first the authors used a 10 per cent solution but soon found that the caustic effect was inadequate. One bronchial occlusion (accessory lobe) resulted from a single application and one occlusion resulted from three applications to the accessory or subcardiac lobe. The rest of the experiments were made with 25 per cent acriflavine. In this group occlusion resulted with great regularity. No abscess formation occurred and, microscopically, damage to blood vessels was not observed. All the different bronchi have been completely stenosed. In several cases the entire lung has been made to collapse completely as the result of occlusion of all its bronchi.

Tuberculosis and Allergic Diseases.—Bray summarizes the association between tuberculosis and asthma as follows: 1. Only one asthmatic patient in a hundred gives any positive evidence of active tuberculosis. 2. Only one patient with active tuberculosis in two hundred suffers from true asthma. 3. When asthma does develop in a tuberculous subject, the sensitizing agent is generally of an inhalant nature and the asthma is relieved by its removal or by a course of specific desensitizing injections. In the rare cases in which the sensitizing agent is bacterial in nature, it is more often a secondary invader than the tubercle bacillus.

Diagnosis of Intracranial Tumor.—Garland points out that any condition producing a rise of intracranial pressure or any localized lesion of the brain may in certain circumstances simulate cerebral tumor. One of the first conditions to consider is renal disease, in which there may be headache, vomiting and papilledema, sometimes associated with transient hemiplegia or monoplegia. The diagnosis depends on examination of the urine, the blood pressure (which is always raised in such a case) and the blood urea. Cerebral abscess does not often give rise to difficulty, as there is usually a history of recent disease of the ear. Papilledema is often absent in cases of cerebral abscess. Hydrocephalus following meningitis should not give rise to difficulty, but sometimes hydrocephalus complicates disease of the middle ear. This condition, which is called otitic hydrocephalus, is associated with high grade papilledema and is of doubtful origin. Cerebral aneurysm rarely simulates tumor, for the reason that aneurysms are usually small and give rise to symptoms only when they rupture. Neurosyphilis may simulate tumor in several ways: the early mental symptoms of a tumor sometimes resemble those of dementia paralytica of the insane, and in both epilepsy may occur. Gumma is a rare condition. Careful examination of the pupils, combined with serologic tests of the blood and cerebrospinal fluid, should prevent an error in diagnosis. Cerebral arteriosclerosis unassociated with renal changes produces an infinite variety of clinical signs which may resemble cerebral

tumor, and it is probably the frequency of vascular disease that makes the diagnosis of cerebral tumor much more difficult in middle-aged and older people.

Tetanus Treated with Curare.—Among nineteen cases of tetanus, Cole presents two treated with curare. Eleven of these patients recovered. All of them, including the two who received curare, were treated on the same general lines, each being given a large dose of antitoxin by the intravenous route as early as possible and before the wound had been touched. The first case treated with curare was the most severe of those in which recovery occurred. Curare seemed to reduce the continuous rigidity of the limbs, abdomen and jaw, to lessen reflex excitability and to lessen the frequency and duration of the spasms in both cases. In the second case the severe spasms, induced by attempting to suck fluid and even by the sight of fluid, were stopped and swallowing was made possible. In the first case, in which the dose was relatively small, the action of the drug was apparent about two hours after the first injection. The effect appeared to last about forty-eight hours. In the second case the effect appeared five minutes after the injection. It is possible that in the first case the action was sufficient to tide the patient over the critical period of the illness by preventing exhaustion and by allowing more food to be given. No unpleasant symptoms were observed while the drug was being given and respiration did not appear to be affected in any way. No serious after-effects were noted, though it is possible that the rather prolonged weakness and wasting of the muscles of the arms and legs may have been due to the curare. The second case was of such rapid onset (incubation period forty-eight hours) and so severe that there was no chance of recovery. Treatment might have been more effective

in prolonging life if it had been begun a few hours earlier. Given, however, when rigidity was continuous and when the reflex spasms were most severe and occurred every thirty seconds, curare checked the spasms, stopped the reflex excitability and lessened the rigidity. Respiratory failure occurred seven hours later when the heart had begun to fail. The results confirm the suggestion that curare or its alkaloids will be useful in the treatment of tetanus. Dosage, however, is at present a difficult problem and will remain so until standardized preparations are available and more is known of the particular actions of its various alkaloids.

Calcium and Phosphorus Metabolism in Osteomalacia.—Hannon and his associates present data on calcium, phosphorus and nitrogen metabolism for thirty-four periods of four days each from a case of relatively early osteomalacia in which no vitamin D therapy had been given prior to the studies. The essential metabolic abnormality in the patient is a lack of absorption of calcium through the intestinal tract, there being no increase in endogenous calcium excretion. The absence of calcium in the urine in the presence of an approximately normal serum calcium level is taken as evidence of conservation of endogenous calcium elimination. Vitamin D administered in relatively small dosage and for a limited period increased remarkably the absorption of calcium and decreased endogenous calcium elimination, thus resulting in a striking calcium and phosphorus retention and deposition in the bone. The beneficial action of vitamin D was sustained for at least four months after its administration was discontinued.

 Biologic Treatment of Injuries of Brain in Course of Infectious Diseases. K. Rachid.—p. 535.

Treatment of Cerebrospinal Meningitis.—The Facatsellis believe that the greatest obstacle to the reduction of mortality from epidemic meningitis lies in the fact that areas of involved meninges become separated by adhesions, thus preventing the free circulation of the serum. The probable solution of this mechanical difficulty consists in the use of multiple routes for bringing the serum in contact with all the diseased parts. The suboccipital route always and the intraventricular, when possible, in addition to the lumbar offer the best hope of fulfilling this purpose. This procedure was applied to fifteen patients, with good results in eleven. Of the remaining four, only two recovered, but the delay in starting treatment in these four was from three to four days. Technically, the suboccipital injection is easy and requires only a little practice. The systematic use of the suboccipital route is possible at all ages. For nurslings the intraventricular route is added to the other two.

 *Therapeutic Action of Certain Renal Extracts in Treatment of Arterial Hypertension. D.-M. Gomez.—p. 1371.

Treatment of Hypertension with Renal Extracts.—Forty patients presenting different forms of arterial hypertension were treated by Gomez with an extract from the cortical region of the kidney. Before treatment was begun the patients were observed almost every day for a control period of about two weeks. The treatment consisted in the hypodermic injection of 5 cc. of the extract daily for from six to eight days. The effect on the minimal and maximal arterial tension, on the blood urea and on the symptomatology were noted. In patients with some signs of renal insufficiency, such as uremia, nocturnal pollakiuria or uremic lesions in the ocular fundi, improvement was the rule. Most of the subjective symptoms disappeared or improved and there was a parallel and lasting decrease in the arterial tension and blood urea. This was true in sixteen of the seventeen more or less uremic patients treated. In the eleven cases of sclerotic hypertension, the results were not quite so good. The results were still less favorable in the four cases of menopausal hypertension treated, although three of four were favorably influenced. In so-called essential hypertension, good results were obtained in only two of eight patients. The author states that advanced cardiac insufficiency is no contraindication for this method of treatment.

Indirect Pain Localizations in Gastric Ulcer.—Ferretti refers to a number of patients presenting gastric and duodenal ulcers with points of pain on costal pressure. He explains these painful points in the following manner: The disease state of the wall of the stomach functions as a primary stimulus, which, conducted by the sympathetic fibers to the cerebrospinal system, arrives at the cortex, where it produces a painful sen-

sation erroneously projected to the corresponding dermatome. This he calls sympathetic intercostal neuralgia. If the stimulus is not sufficiently powerful, and therefore below the threshold, an added stimulus is necessary. In order for this painful stimulus to be perceived in the cortex, a secondary stimulus must be produced. The author believes that this occurs by the pressure of the involved dermatomes and is carried to the cerebral centers by way of the cerebrospinal system. This will also sometimes be referred to the cutaneous terminations (point of pain production). The author concludes that these points of pain are of great value in the diagnosis of gastric and duodenal ulcers.

Encephalography in Cerebral Disturbances During Childhood.—Rupilius discusses the anatomic structure of the cerebrospinal fluid spaces. Exact knowledge of these spaces is an absolute requirement for the interpretation of the roentgenograms. For encephalography the child should be fasting, and sedatives or hypnotics should be given. Of the three possible modes of introduction of air—ventricular, cisternal or lumbar—the author prefers the latter. He never resorts to the cisternal puncture, because it makes movements of the head impossible, which are often necessary for the filling process; moreover, it is difficult in restless children. He resorted to ventricular puncture only in those instances in which air filling of the ventricles from below proved impossible. There were no undesirable complications; on the contrary, this measure often had a therapeutic effect by reducing the pressure. This method is especially simple in nurslings and small children with open fontanel. Lumbar puncture was always done in the sitting position. Kyphotic curvature of the back and a slight forward bending of the head were found advantageous. Immediately following the puncture, the head may be bent back and forth several times. The author used a fine needle and introduced less air than the amount of fluid withdrawn. The quantity of air varied between 10 and 100 cc., but in most instances it was less than 50 cc. The author performed roentgenoscopy immediately following the introduction of air, contrary to the practice of other diagnosticians, who wait several hours. The resorption of the air was controlled by repeated roentgenoscopies. There was no relation between the quantity of air injected and the rapidity of resorption. The author emphasizes that the mere taking of a roentgenogram is insufficient but that roentgenoscopy should be done first in different directions, because if only a portion of the cerebrospinal fluid has been removed roentgenoscopy alone will give a clear picture of the ventricles. Roentgenoscopy and roentgenography must complement each other and each alone is of little value. In encephalographies of nurslings there frequently was an air accumulation on the surface of the brain, while the filling of the ventricles met with difficulties. Encephalography has a much wider application in children than in adults, for, while in adults it is employed mostly for the diagnosis of tumors, in children it is resorted to generally in chronic inflammations of the brain or its meninges. In acute processes some investigators have seen exacerbations result after encephalography, but the author never made such an observation. In epidemic encephalitis the evacuation of the cerebrospinal fluid by air inflation has been known to produce therapeutic effects. Moreover, encephalography reveals the further changes in the brain, such as the development of hydrocephalus. In congenital or obstetric cerebral defects, encephalography often gives clear pictures of the changes. In convulsions of an epileptic or an obscure nature, encephalography may permit a differentiation between genuine and residual epilepsy. The author assumes a genuine epilepsy only if the picture reveals no gross defects.

Pathologic pictures may indicate former inflammatory or traumatic changes. In cases of hemiplegia, contralateral changes were frequently detected. This made possible an exact localization and was thus an important factor in the successful operative removal of the focus. Interesting and typical pictures were obtained also in cases of cerebral paralysis, idiocy and imbecility.

Cardiac Disturbances of Nurslings with Dysentery.—Von Kiss points out that, from the standpoint of cardiac disturbances, dysentery of nurslings can be divided into two stages. During the early stage of dysentery, the cardiac changes are primarily functional. There is a severe tachycardia and a pathologic dilatation of the coronary vessels. Anatomic changes, if present at all during this time, are limited to certain elements in the sino-auricular node and to the muscles immediately surrounding it. In the later course of the disease, the heart shows symptoms of wear. The cardiac changes are produced by the pathogenic organisms of dysentery or by the toxins of these organisms. Other factors are the secondarily developed acidosis, azotemia, exsiccosis, changes in the osmotic condition, damage to the vasomotor system, the peculiar function of the kidney of nurslings, and in addition to this probably the *B. coli* infection and the resorption of the pathologic products of disintegration. During the early stage it is important that the nursling be kept absolutely quiet. The nursing should be treated like a patient with heart disease in the severest stage of decompensation. Transfusion of large amounts of blood or injection of great quantities of dextrose solution of high concentration, as well as epinephrine and medicaments with a similar action, are contraindicated during the early stage. Instead the author recommends a large dose of digitalis and the intravenous administration of from 10 to 12 cc. of physiologic solution of sodium chloride with 5 or 8 per cent of dextrose for each kilogram of body weight. If necessary, this measure may be repeated within twenty-four hours. In the later stages of the disease it is advisable to give digitalis in small doses and small quantities of a 20 per cent solution of dextrose alternately with small blood transfusions.

Sympathetic Nervous System and Menstruation in Pulmonary Tuberculosis.—Smilovits shows that in tuberculosis the sympathetic nervous system undergoes alterations which result in changes in single and in synergistic organ functions. They become manifest in alterations of the metabolism and in allergic processes and thus influence the course of the tuberculosis. The extragenital functional waves of the female organism are only distant actions of the ovarian activity and develop through the mediation of the sympathetic correlation. Within the state of equilibrium there exists a sympathetic instability, to which the author ascribes the premenstrual hyperthermia of the healthy woman. The menstrual disturbances that occur in tuberculosis, such as changes in the duration, the intensity and the interval, and amenorrhea or dysmenorrhea, are caused by processes of degeneration in the ovarian parenchyma, which are the result of the action of tuberculous toxins. The premenstrual hyperthermia indicates an active process in the woman with pulmonary tuberculosis only if the decrease of the hyperthermia is retarded. The menstrual and postmenstrual hyperthermias, however, indicate a toxic condition. The more prolonged the menstrual and postmenstrual hyperthermias and the shorter the nonfebrile interval, the greater is the progressiveness of the pulmonary process. The menstrual manifestations indicate only the condition existing at the time. The pulmonary process is not necessarily unfavorably influenced by the menstruation. The manifestations are the result of a sympathetic hyperirritability, which sensitizes the temperature center for toxins eliminated in increased quan-

ties during menstruation. The temporary decrease in immunity that occurs during menstruation is insignificant. The author thinks that at the change of the seasons, particularly in the spring, the concurrence of an increased sympathetic irritability and of an increased allergic state may eventually result in a menstrual reactivation of the tuberculous process. He shows that the general conservative measures and some of the local treatments (collapse therapy) exert their influence by way of the sympathetic nervous system. Substitutional organotherapy has failed in tuberculosis; however, all menstrual disturbances in tuberculosis can be influenced favorably by medicaments that have a central and a peripheral action, by a belladonna preparation, ergotamine and phenylethylbarbituric acid.

Calcium Content of Serum in Tuberculous Persons.—In studies on the serum of patients with tuberculosis, Kurakane observed that the calcium content of the blood influences the sedimentation speed of the erythrocytes. The lower the calcium content the greater is the sedimentation speed. The author shows, however, that this rule applies only to female patients.

Infection with *Bacillus Botulinus*.—Hürthle and Gross report the histories of two patients who, after eating blood sausage and canned beans, suddenly developed bulbar symptoms: impairments of the muscles of the eye with disturbances of movement and accommodation, of the facial nerve (cessation of salivation), of the glossopharyngeal nerve (disturbances in swallowing) and of the vagus nerve (gastro-intestinal symptoms). In one of the patients a paralysis of the left phrenic nerve existed for some time, and in the other one gastro-enteritis accompanied the botulism. The author considers the two cases noteworthy because they demonstrate the favorable influence of large doses of serum; one patient received twice 100 cc. of serum and the other 150 and 100 cc.

Arthritis Caused by Paratyphoid Bacilli.—Ruiz Gijón relates the history of a youth, aged 18, who had a severe inflammation of the right hip joint. The roentgenologic aspects indicated an osteomyelitic process. The incision of the joint yielded a thick, yellow-gray, creamy pus, the bacteriologic culture of which showed paratyphoid B in pure culture. The agglutination in the blood was positive in a dilution of 1:800 and the blood culture was likewise positive. The urine and feces were free from bacilli. The first intervention on the joint led to no improvement, and a second one was done. The second operation revealed extensive necroses of the cartilages but no impairment of the bone. The necroses were removed. The joint was left open and was irrigated daily. Under this treatment, improvement was comparatively rapid. The author states that paratyphoid infections of the joints have been known almost as long as the paratyphoid bacilli. The majority of cases thus far reported, however, either accompanied or immediately followed a paratyphoid infection. Moreover, in the majority of cases it was paratyphoid N that caused the articular disturbance. In this case the previous history showed no record of paratyphoid. Repeated tests on stools and feces yielded no paratyphoid bacilli, and tests on the excreta of mother and sister likewise remained negative. At the age of 1 year the patient had had a coxitis, and the author assumes that the impairment of the joint at that time may be a factor in the development of the present process, as a previous trauma plays a part in the articular localization of paratyphoid infection.

Atony of Small Intestine in Disorders of Hepatobiliary System.—In the course of roentgenologic studies on the small intestine, Bayer noted that in cholecystopathies the roentgenograms of the small intestine show certain characteristics in the time of passage as well as in the shape of the intestinal loops. The passage is retarded and the intestinal loops are dilated, which indicates that the hepatobiliary diseases influence the peristalsis and the tonus of the small intestine. In an attempt to explain this behavior of the small intestine during hepatobiliary disorders, he points out that the bile has an inhibiting influence on the smooth muscles and that, if bile enters the blood, the tonus and the peristalsis are reduced.

Early Infantile Progressive Spinal Muscular Atrophy.—Schildknecht shows that early infantile progressive spinal muscular atrophy is characterized by a continuous progress of the disorder, which seems to be the only symptom that permits a sure differentiation from myotonia. Familial occurrence and the time of development of the first symptoms may be characteristic in some cases but are not of decisive significance. The pathologic-anatomic examination reveals degeneration of the pyramidal cells in the anterior central convolution with predominance of a process leading to atrophy, severe degeneration of the motor cells of the anterior horn of the spinal cord with considerable reduction in their number, degenerative processes in the peripheral nerves, degenerative changes in the terminal motor plates and atrophy of the paralyzed muscles. A comparison with myotonia (on the basis of the studies of Bickel-schowsky) leads the author to the conclusion that early infantile progressive spinal muscular atrophy (Werdnig-Hoffmann's disease) is essentially a progressive degeneration of nerve cells, which leads to retrogressive processes in the muscles and the terminal motor plates and which differs essentially from myotonia. The definite pathologic-anatomic diagnosis necessitates still other investigations, particularly the examination of the terminal motor organs. This point gives the best prospects for a better insight into the nature of early infantile progressive spinal muscular atrophy.

Postencephalitic Visual Spasms.—Engerth describes a case of postencephalitic visual spasm with peculiar symptoms. Immediately before and during the attacks of visual spasm, states of anxiety and thoughts of compulsion exist. The patient, aged 17, becomes obsessed with the idea that he will have to leave home in order to recover, but at the same time he fears that he cannot move during the spasm. At the severest stage of the visual spasm, he has thoughts of suicide. A somnolent state terminates the visual spasm. After awakening, the patient is in a euphoric state, but at this time he occasionally carries out this compulsion idea. He runs away from home and cannot be held back by anything. His memory for happenings and acts during this time is deficient. The author attempts to show the relations between compulsion ideas, destructive bent, somnolence as the neutralization of the destructive inclination, and the carrying out of the compulsion idea. The case illustrates that the visual spasm, the subsequent sleep and the compulsory action after awakening must be considered as a coherent disease process. Because of the criminal action committed in the course of a compulsory flight, the case is of importance for forensic medicine.

Autocerebrospinal Fluid Treatment in Poliomyelitis.—Török describes the method he employed in the treatment of forty-nine cases. Immunization was done by means of intramuscular injection of equal parts of blood from convalescents and from adults. Small children were given from 30 to 40 cc., older ones from 40 to 50. At the same time from 15 to 20 cc. of the spinal punctate was injected intramuscularly. Cerebrospinal fluid was withdrawn every second day. The usual amount was from 30 to 40 cc. Half of this quantity was injected on the day of withdrawal and the other half on the following day. In patients in whom the treatment was begun during the preparalytic stage, the injections were continued until the fibrinogen reaction became negative, which as a rule was after about eight injections. The patients with acute paralytic symptoms were given twelve injections. In some cases the injection of the blood from convalescents and adults was repeated after several days. The author points out that in acute anterior poliomyelitis it is difficult to estimate the results of a therapeutic method, but the statistical comparison of his material with that of others shows that the combination therapy produced more favorable results. Among the factors that led to a trial with the autocerebrospinal fluid therapy was the observation that in pleuritic processes, for instance, the parenteral administration of several cubic centimeters of the exudate may exert a favorable effect on the resorption of the exudate.

Effects of Venesection.—Hitzengerber shows that in patients with arterial hypoxemia venesection improves the oxygen saturation of the arterial blood. The oxyhemoglobin content of the arterial blood becomes absolutely or relatively improved in these patients. The pathologically increased carbon dioxide content of the arterial blood is reduced by venesection. In patients with pneumonia, who have an abnormally low carbon dioxide content of the arterial blood, venesection brings the values near to normal. However, venesection produces no appreciable changes in patients in whom the oxygen and carbon dioxide contents are normal. The author gained the impression that the described results of venesection persist for about fourteen days. He thinks that venesection is indicated in hypoxemia of pulmonary origin and that approximately 500 cc. must be withdrawn to effect an improvement in hypoxemia.

Determination of Velocity of Blood.—Homma describes a method that permits the measurement of the velocity of blood in the vein of the arm. The method consists in the intravenous administration of a small drop of iodized poppy-seed oil or of iodized sesame oil before the roentgen screen, and in determining with a stop watch the time that is required for this drop to travel between two points that have been marked on the arm by means of two strips of sheet lead. The strips are usually placed about 10 cm. apart, the distal one about 3 cm. proximal from the bend of the elbow. The syringe as well as the oil is brought to approximate body temperature. The injecting needle is placed into the vein either without stasis or after a short stasis. After the examiner has made sure that the needle is in the vein, the light is turned off and the position before the screen is taken so that the needle as well

as the two lead marks on the arm are visible on the screen. Then the injection is made with the right hand while the left one holds a stop watch. If the oil has the correct temperature (between 30 and 40 C.), one or several little drops are formed and are carried along by the blood stream; the stop watch determines how much time is required to cover the distance between the two marks. The injection should not be made immediately after the stasis, because a change in the velocity is caused by the stasis; but it is also inadvisable to leave the needle in the vein too long. The author thinks that it will generally be possible to inject before the lapse of thirty seconds. In describing his experiences with this method, he points out that double determinations reveal either a greater velocity in the basilic vein than in the cephalic vein or the same velocity in the two vessels; rarely is the blood stream slower in the basilic vein. The velocity of the blood stream varies considerably in different persons. The author differentiates three types. He considers the circulation slow in the persons in whom the velocity is less than 1.5 cm. a second, average when it is between 1.5 and 4 cm., and fast when it is more than 4 cm. He shows that the method involves no danger, is simple and exact, and has clinical value.

Combined Arsenic-Gold Therapy in Lupus Erythematoses.—The method recommended by Steiner consists in the prolonged oral administration of arsenic in the form of solution of potassium arsenite mixed in equal parts with tincture of ferrated extract of apples and in a series of injections of an oily emulsion of gold. At first three drops of the mixed solution are given three times daily. This dose is increased daily or every second day by one drop until signs of arsenic irritation commence to appear (local inflammation and dissemination of small, new erythemas, eventually also cutaneous itching, dryness of the pharynx and burning of the eyes). The maximal dose should be from fifteen to twenty drops three times daily. As soon as signs of irritation appear the dose of the arsenic medication is rapidly decreased, but the arsenic medication should never be stopped suddenly, even if severe signs of irritation are present, for this would intensify the symptoms. At the time when the arsenic dose is rather high, at any rate when the patient is under a sufficient arsenic action, the intragluteal injection of the gold emulsion is begun. At first a 2 per cent oil suspension of aurothiodextrose is given in gradually increasing doses, and later increasing doses of a 20 per cent emulsion are administered. The highest single dose of the 20 per cent suspension of aurothiodextrose is 0.06 Gm., and it is reached after from twelve to fifteen injections. The highest doses (0.04, 0.05, 0.06 Gm.) are repeated from three to four times. The intervals between injections are from five to seven days. The total amount of gold suspension administered during the entire treatment is approximately 0.5 Gm. The result of this procedure was that fourteen of nineteen patients with lupus erythematoses were cured in from two to three months. Nearly all of these patients had previously been unsuccessfully treated with other remedies. The cases with considerable dissemination seem to be especially suitable for this treatment. A complete explanation of the mode of action of the combined arsenic-gold therapy cannot be given as yet. However, the author assumes that arsenic changes the capillary walls to such an extent that the penetration of the gold salt into the tissues is promoted and the gold action thereby increased.

Diathermy and Histamine in Polyarthritides.—In cases in which, after a previous acute polyarthritides, relapses developed so that the disorder was in the subacute or the chronic stage, Dzinich resorted to the injection of histamine and to diathermy. The subcutaneous injections were begun with 0.5 mg. of histamine, and, when there was no noticeable reaction, the dose was increased to 1 mg. The injections were usually made near the involved joints. In the beginning of the histamine reaction, diathermy was applied to the diseased joint for twenty minutes. These treatments had to be given from ten to twenty times and in a few cases more often. Of thirteen patients treated in this manner, five were cured, five greatly improved, two slightly improved and one remained uninfluenced. The author thinks that further trials with the method are justified. He ascribes the efficacy of the treatment to three factors: (1) the desensitizing action of histamine, (2) the general physical

action, and (3) the deep hyperemia produced by the diathermy in addition to the more superficial vasodilatory action of histamine.

Treatment of Anaphylactic Shock and Serum Disease.—Buzello states that foreign proteins when injected into the human body circulate in the blood for some time in the original state. These substances are rendered harmless by the formation of antibodies, which become bound down to certain cells and are demonstrable in the blood. This process is referred to as hypersensitivity or anaphylaxis. During this period the introduced proteins referred to now as antigens become converted from freely soluble albumins and globulins into more or less insoluble ones. Anaphylaxis develops from seven to ten days after the injection of the serum. Once established, it persists for a long time, even a lifetime. Serum shock and serum sickness are due to the reaction between the bound down antibodies and the still undissolved protein substances. The human body can react to serum injection in one of two ways: with an immediate reaction or anaphylactic shock, or with a late reaction or serum sickness. Anaphylactic shock may take place in a previously injected person, as well as after the first injection. Its occurrence is favored by a congenital or hereditary susceptibility or allergy. On the whole, its occurrence is rare. It develops most frequently following an intravenous injection in a person previously treated with the same serum. It is manifested by pallor, chills, vomiting, cold sweat, small fast pulse, fall in the blood pressure and ensuing circulatory failure. This may lead to collapse, widely dilated pupils, dyspnea and convulsions. The author suggests immediate cessation of further injection and exhibition of a cardiac stimulant (2 cc. of pentamethylene tetrazol). Next, 1 cc. of 1:1,000 epinephrine is administered, either alone or in physiologic solution of sodium chloride. Starck recently showed that symptoms of anaphylactic shock are improved by induction of a mild degree of ether narcosis. The slower the serum is injected, the less likelihood there is of a shock. The author therefore insists that serums should preferably be injected hypodermically, possibly intramuscularly, but never intravenously. One should inquire beforehand into the possible sensitivity of the patient as revealed by a history of hay fever or asthma. A positive history suggests that the patient is allergic and that other than horse serum should be used in his case. Serum disease is much more frequent than anaphylactic shock. It may likewise occur after a repeated injection or after the first injection. Its symptoms develop from the fourth to the seventh day in a previously injected person, and from the seventh to the ninth day after the first injection. At the seat of injection there develop redness, edema and burning pain. There are headache, fatigue, fever, generalized urticaria, chills, sweats, and bone and joint pains. Diarrhea and circulatory failure may develop. Symptoms persist for four or five days and disappear without leaving ill effects. In children under the age of 10 years, cardiac failure and edema of the glottis may give concern. Treatment consists in support of the circulation and exhibition of some calcium salt. It occurred to the author that, since the serum disease represents the reaction between the antibodies and the still undissolved antigens, a repetition of the injection at the right moment could abolish or at least diminish that reaction by furnishing the body new antigens, so that a surplus of antigens is present. He was surprised at the good results following this treatment both in patients with severe symptoms of serum disease and in patients with beginning manifestations of it. A number of patients thus treated were followed up for some time and there was not another case of serum disease observed.

Radium Treatment in Benign Genital Hemorrhages.—Naujoks and Hoffmann relate their experiences with radium therapy in benign genital disorders. Metrorrhagias and abnormally profuse menstrual hemorrhages in women more than 40 years of age were the most frequent indication for radium treatment. Rarer indications were diseases of blood, such as leukemia and essential thrombopenia, also tuberculosis of the endometrium, juvenile menorrhagias and sterilization. The authors made their observations on 285 women, 252 of these having premenopausal or menopausal hemorrhages. In describing the technic, they point out that they always precede the introduction of the radium tube by an abrasion. Following this, a radium preparation, 50 mg. in weight, enclosed in a brass filter of 1 mm. wall thickness, 6 mm. in length and covered by a thin rubber membrane, is introduced. The lower portion of the cervical canal and the vaginal vault are filled with gauze, so as to prevent the tube from sliding down into the vagina. In order to facilitate the discharge from the uterus during the one or two days the radium preparation is retained, a strip of gauze is placed alongside the radium container and led outward past the external uterine os. The tamponade of the vagina and particularly of the posterior vaginal vault not only aims at fixing the container but also exerts an upward and forward pressing of the uterus so as to remove it as far as possible from the ovaries. The authors emphasize the necessity of complete asepsis in the application of the radium. In discussing the dosage, they point out that some radiologists have recommended small doses, while others advised rather large ones. They themselves are in favor of the larger doses, from 2,000 to 2,400 mg. element hours. After-examinations of 213 cases revealed that radium treatment had failed in only two of these cases and both of these women had myoma. In the so-called menopausal hemorrhages, radium treatment was almost 100 per cent effective. The authors think that the symptoms of abolished function that may develop after radium treatment are not sufficiently severe to be considered a contraindication to it. They conclude that intra-uterine radium therapy deserves a prominent place in the treatment of benign gynecologic disorders.

Tonsils and Mammary Glands During Puberty.—Peller and Zimmermann continued Peller's studies, in which were demonstrated the inhibiting influence of the tonsils on the growth in height and in weight, on the development of the thorax and on the menarche, and the promoting influence of the tonsils on the photochemical defense reaction of the skin. In this paper they report their observations on the relations between tonsils and the mammary glands. They gained the impression that the tonsils inhibit the puberal development of the mammary glands, for girls who had undergone tonsillectomy showed an earlier development. It is assumed that the tonsils influence the maturation of the mammary glands not directly but indirectly by way of the general development.

Site of Formation of Gonadotropic Substances.—Remzi relates the histories of two women. One died shortly after operation for cystic mole and the other one after an operation for chorionepithelioma. The urines of both patients contained large amounts of gonadotropic hormones and the implantation of parts of the operative specimens gave positive reactions I, II and III in the Aschheim-Zondek test. Implantation of parts of the anterior lobe of the hypophysis that had been removed in both patients during necropsy, however, gave negative Aschheim-Zondek reactions, which proves that the hypophysis contained no gonadotropic substances. The author points out that other investigators of the gonadotropic sub-

stances found in the urine during pregnancy, cystic mole and chorionepithelioma have suggested other, extrahypophyseal, origins, such as placental or chorionic sources. The fact that the hormone production is especially profuse in cystic mole and in chorionepithelioma, that is, in conditions with chorionic proliferation, seems to speak for a chorionic origin. However, nothing definite can be said about the site of origin of the gonadotropic substances. The author mentions several experiments that according to Aschheim's suggestion should be carried out in order to determine the hypophyseal origin of these substances.

 *Cases of Ovarian Carcinoma Treated at Gynecologic Clinic in Helsingfors from 1919 to 1933. C. von Numers.—p. 720.

Ovarian Carcinoma.—Von Numers says that of the 151 cases of ovarian carcinoma in which treatment was given at the gynecologic clinic in Helsingfors from 1919 to 1933 only seventeen, or 11.3 per cent, were surely secondary. The average age of the patients was 49.1 years; marked increase in the frequency of ovarian carcinoma appeared between 35 and 40, and the greatest number of cases occurred between 45 and 50. Of the entire number of cases 46.6 per cent, and of the secondary carcinomas 88.2 per cent, were bilateral. There was no definite deviation from the normal in the average age of the menarche and the frequency of sterility, but the average fertility was somewhat lower than usual in Finland. There was no evidence of greater disposition to ovarian carcinoma among unmarried women. Ascites was present in 39.1 per cent of all cases. Eighty-two, or 55.8 per cent, were in an operable condition. The primary operative mortality was 7.3 per cent. Observation for at least five years showed an absolute percentage of recovery of 17.8 and a relative percentage of 38.1, exclusive of the secondary cases. No notable effect of post-operative roentgen treatment could be determined.

Cancer of Stomach.—Bull's material comprises 289 cases, 206 in men and 83 in women, the fate of all but five being known. Radical operation was performed in 23.3 per cent of the men and 30 per cent of the women. In 20.2 per cent of the cases in which operation could not be performed, clinical symptoms had been present for only one to five months. The author states that the patients with cancer of the stomach who undergo resection have an average life duration from five to six times longer than the patients in the other groups and he urges that in operation every effort be made to perform resection. The results of the operation depend fully as much on the degree of malignancy of the cancer in each case as on its clinical duration. Tabulated review is given of the eleven patients still living from three and three fourths to thirteen and a half years after resection and of the five cases in which death occurred from recurrence after from three and a third to nine years after resection.

Rheumatic Arteritis and Rheumatic Nodes.—Harbitz asserts that there is a rheumatic arteritis analogous to rheumatic inflammation of the heart musculature and in and around the joints; it is characteristic to a certain degree and extensive enough to be of great importance. He is inclined to believe that there is also a "visceral febrile rheumatism" which does not affect the joints, localized to the heart and blood vessels and possibly other internal organs (including the kidneys), and that this visceral rheumatism is the basis for certain grave and even fatal disorders.

STUDIES ON MORPHINE ADDICTION PROBLEM

CHARLES W. EDMUNDS, M.D.

NATHAN B. EDDY, M.D.

ANN ARBOR, MICH.

AND

LYNDON F. SMALL, Ph.D.

CHARLOTTESVILLE, VA.

In the last few years there has been a great increase in the interest taken in the general subject of drug addiction not only in the United States but also in practically every other country on the globe. This is easily understandable in those countries where drug addicts are numerous, but among those nations where today addiction is not a serious problem hearty cooperation has also been encountered and may be considered possibly as a measure of self protection. Two or three significant features of this interest in the problem may be mentioned. Of first importance is the Geneva Convention of 1931, under the terms of which fifty-five nations have agreed to limit the manufacture of narcotic drugs to a quantity necessary for medical and scientific purposes and have placed the control of such substances under a committee of the League of Nations. Under the terms of this agreement, each nation notifies the committee each year of its legitimate needs of these drugs for medicinal purposes. The nations make a quarterly report of the stocks on hand and of their consumption of these products. Further, the agreement makes it theoretically, and to a large extent practically, possible to control the manufacture of all drugs capable of producing addiction and to trace them through all legitimate channels to their ultimate destination.

A second matter of great interest in this country has been the decision of the government to establish a federal hospital where persons suffering from addiction may go for treatment. This hospital, which is located at Lexington, Ky., is now under construction and will probably be opened in the early months of 1935.

A further step in the solution of the addiction problem as it is being studied in this country is to be found in the cooperative research that is being carried on under the National Research Council in the Universities of Virginia and Michigan in conjunction with various branches of the government service, especially the Bureau of Narcotics and the Public Health Service. The funds for the research were derived in the first instance from the Bureau of Social Hygiene, this agency

being replaced in January 1933 by the Rockefeller Foundation, which organization assumed responsibility for the support of the undertaking for a period of three years. The plan underlying the research as it has been adopted by the committee having direct supervision of the work has been to endeavor to find some drug or drugs that may be used to replace morphine in some of the various ways in which it is used in medicine—drugs that may possess some of its valuable medicinal properties but do not lead to addiction. A somewhat similar plan of work was undertaken for a solution of a like problem in the case of cocaine. This alkaloid, which possesses valuable anesthetic properties, also is highly addicting. A search for a substitute resulted in the finding of procaine, an effective local anesthetic devoid of addicting qualities. It may well be questioned whether the injection of cocaine should not be totally prohibited as it is in Germany, and thus one source of danger of addiction be removed.

The general plan of the present search for a morphine substitute, then, has been to make an accurate study of morphine itself—the chemical constitution in relation to its various actions; the importance of the phenanthrene nucleus, of the side chains attached to the nucleus and of the part each plays in the final picture of the drug's action. The method of attack has been twofold—a breaking down of the morphine molecule and a building up of a compound more or less like morphine, starting with the phenanthrene nucleus as a basis and gradually adding on side chains, the change in activity being observed as each modification is made.

The work on the chemical side of the problem has been carried on in the University of Virginia, where some 190 different compounds have been prepared and sent to Ann Arbor, where they have been studied in the Pharmacological Laboratory, morphine itself being used as a standard of comparison.

The various actions that have been studied aside from the general toxicity of the compounds have been their effects on the general activity of the experimental animals, whether they are depressed or excited; the effects on the respiration and the gastro-intestinal tract; the emetic action, and finally the presence or absence of any analgesic property in the compound. Whether any of the substances possess addicting properties is very difficult to determine on animals, although efforts are being made to study this aspect of the problem on dogs and monkeys. However, the final test will have to be made on the human patient and here the committee has the invaluable assistance of the federal Public Health Service.

An important and interesting aspect of the pharmacologic portion of the work and a subject of fundamental importance has been the comparative study of various

pairs or groups of compounds that differ from each other in only one respect, usually a substitution or change in one side chain attached to the phenanthrene nucleus. Such a comparison may be made, for instance, in the action of morphine and codeine, in which a hydroxyl group in the former is replaced by a methoxyl group in the latter. The chemists of Virginia have furnished many such pairs of compounds, which have made possible comparative studies leading to the formulation of certain rules as to the action of the outlying groups and their importance in the morphine picture, thus furnishing an interesting contribution to the subject of chemotherapy.

In figure 1 are shown the formulas for morphine and codeine. They are seen to consist of the central phenanthrene nucleus, with an oxygen bridge, a nitrogen containing ring, hydroxyl groups and hydrogen atoms attached. The hydrogen of one of the hydroxyls in morphine being replaced by a methyl group in codeine. Thus in codeine the phenolic hydroxyl of morphine is inactivated or muzzled by the methyl group and a comparative study of these two compounds yields information as to the importance of this group in the morphine effect. As is common medical knowledge, codeine differs from morphine in being less depressant and more convulsant, in possessing less analgesic action and less effect on the respiration and the intestine. The relation of the comparative effects of these two alkaloids holds good also for the other similar compounds in the morphine series. Fifteen pairs of derivatives allied to morphine, each member differing from its sister com-

of that portion of the molecule to which it is related. The ring to which the alcoholic hydroxyl is attached is aliphatic in character, while the phenolic hydroxyl is connected to an aromatic ring.

The alcoholic hydroxyl also can be muzzled by methylation, by acetylation or by halogen substitution and in this case too there is a uniform change in activity as a result of the chemical change. A study of twelve pairs of such compounds shows an increase in activity, in every case affecting especially the analgesic and respiratory effects. The alcoholic hydroxyl in the 6-position, therefore, appears to be inhibitory to these actions of morphine, because when its activity is suppressed chemically these effects of the molecule are greatly enhanced.

The differences in the hydroxyls chemically and pharmacologically are well illustrated in figure 1 and the table.

In the comparisons shown in the table it will be noted that while methylation of the phenolic hydroxyl has decreased analgesic, respiratory, depressant and intestinal effects and methylation of the alcoholic hydroxyl has increased the same actions above those exhibited by morphine, muzzling either hydroxyl has increased convulsant action and decreased emetic effect. It has been found generally true that any chemical modification of the hydroxyl

Fig. 2.—The desoxymorphines.

Fig. 1.—Formulas for morphine and codeine. Figures within morphine molecule indicate system of numbering of carbon atoms of the phenanthrene nucleus.

pound only as codeine differs from morphine, have been prepared and studied and in every case the same rule holds good, so that it would seem reasonable to conclude that the presence of the free phenolic hydroxyl is important for the depressant and analgesic action of morphine as well as for its effect on respiration.

Although it is symmetrically placed in relation to the phenanthrene nucleus, the second hydroxyl of morphine differs from the first in its chemical nature, being alcoholic rather than phenolic, and in the chemical properties

* Both codeine and heterocodeine produced nausea only in amounts well above the analgesic dose, while morphine caused vomiting in less than the analgesic dose.

groups in compounds of the morphine series decreases emetic action, suggesting a causal relationship between free hydroxyls and the production of emesis. This is further emphasized by the increased incidence of vomiting that results if an additional free hydroxyl group is introduced.

The importance of the hydroxyl group in the production of certain of the morphine effects is also shown by a study of the change in the action of phenanthrene itself when hydroxyl groups are attached to the nucleus. Phenanthrene is relatively inactive, displaying only a mild hypnotic effect, but when a hydroxyl group is inserted in the 3-position (as in the case of the phenolic hydroxyl in morphine) an increase in depressant effect

is seen and some degree of analgesic action appears. If a second hydroxyl group is inserted in the phenanthrene nucleus these actions are still further strengthened, especially the analgesic, depressant, emetic and toxic effects.

The rôle of the alcoholic hydroxyl in morphine can be still further elucidated by its total removal and its replacement by hydrogen or oxygen. In the first instance this change results in formation of the type of compounds shown in figure 2, the desoxymorphines. Dihydrodesoxymorphine-D, one of this series, is a very active compound, only about three times as toxic as morphine, but exerting an analgesic action at least ten times greater and a general depressant effect some thirty or forty times as great as morphine. It seems also to be entirely devoid of emetic effect. On account of these properties, which appear to be valuable, this compound is being subjected to clinical trial at the present time. In the second group of changes mentioned, namely, the replacement of the alcoholic hydroxyl by oxygen, compounds of the type of dilaudid and dicodid are produced, both of which have been used in clinical practice.

A second feature of the morphine molecule that is certainly of vital importance is the nitrogen-containing ring. Although the exact position of this ring in the morphine molecule is not known with absolute certainty, any modification of it (for example, the opening of the ring, transforming it into an open chain, fig. 3) results in a great loss of typical morphine effects. In spite of this interesting and important observation, it has been found that the attachment of a somewhat similar nitrogen-containing open chain to the phenanthrene nucleus (fig. 3)

Fig. 3. — Diethylaminomethyl-3-phenanthryl carbinol and alpha-methylmorphimethine.

Mosettig and his co-workers, who are devoting their entire time to this phase of the work. It should be finally pointed out, however, that while the phenanthrene nucleus exhibits very interesting activities, especially in the form of the derivatives which have been synthesized, it has never been proved that it is really the essential or necessary portion of the morphine molecule. On that account it has not seemed wise to confine the synthetic work entirely to phenanthrene. It has been extended to include the next most promising substance worthy of study, which appeared to be diphenylene oxide (fig. 4).

A series of compounds is being synthesized with this grouping as a base. The parent substance is seen to consist of two phenyl groups connected through adjacent carbon atoms and possessing an oxygen bridge as in morphine. Diphenylene oxide exhibits an activity somewhat comparable to phenanthrene, but its derivatives are in some respects more active. In the building

Fig. 4.—Diphenylene oxide.

up of the diphenylene oxide derivatives, many of the same groups have been added as in the phenanthrene series, permitting direct comparisons of pairs of substances having on the one hand a phenanthrene nucleus and on the other a diphenylene oxide base. When such comparisons are made, the latter are more toxic but often possess the greater analgesic action. None of them have exhibited typical morphine-like action.

From this brief survey of the work, it will be seen that notable progress has been made in the correlation of chemical structure to physiologic activity as applied to the morphine series and in the development of morphine-like effects in comparatively simple derivatives of phenanthrene. This progress has been possible only through the cooperation of many agencies—the Rockefeller Foundation, which is furnishing the necessary funds; the Universities of Michigan and Virginia, which are contributing the laboratory facilities; the Bureau of Narcotics and the Public Health Service, which has undertaken the clinical aspects of the problem, and finally the laboratory personnel, whose enthusiastic and indefatigable efforts are pressing toward a solution of the problem.

Case Records and Self Education.—I have a very definite impression that the average interne quite fails to grasp the full significance of case records. He may realize that from a medical point of view they are important as a basis for the study of unusual cases, new procedures, or particular diseases. . . . What he seldom realizes, in my experience, is that they offer one means, and an important means, of self-education. It is, after all, a rather difficult matter to put on paper an adequate and satisfactory history. It is an art in itself, and it is only acquired by experience and practice,—not merely practice in history taking itself, of course, but experience in the physiognomy of disease and in the natural history of the commoner maladies. I have the feeling that in many of our hospitals the interne's attitude of indifference to case records is fostered by the shortcomings of the visiting staff. It is certainly unusual in many hospitals to find in the average case record careful notes dictated by the visiting physicians or surgeon. They, too, do not always realize that the habit of putting down one's observations in writing not only increases descriptive powers but develops capacity for observation and clarifies one's conception of a given case.—Blumer, George: Some Discursive Remarks on Bedside Diagnosis, *Yale J. Biol. & Med.* 6:571 (July) 1934.

THE ADDICTION LIABILITY OF CODEINE

C. K. HIMMELSBACH, M.D.

Assistant Surgeon, U. S. Public Health Service

FORT LEAVENWORTH, KAN.

Discussions have arisen from time to time concerning the addiction liability of codeine and its value as a therapeutic agent for the relief of those withdrawal phenomena seen when morphine is abruptly withheld from persons addicted to its use. Although generally conceded to be nonaddicting, various authors, notably Sollier,¹ Petty,² Lambert,³ White,⁴ Rouges de Fursac and Monestier,⁵ Terry⁶ and Sollmann,⁷ have indicated that codeine possesses this propensity. It was therefore considered advisable to investigate the addiction liability of codeine before employing it in the treatment of abrupt morphine deprivation. The studies with which this article deals, however, attempt to record certain preliminary observations necessary for carrying out a cooperative investigation sponsored by the Committee on Drug Addiction of the Medical Science Division of the National Research Council.

The Committee on Drug Addiction of that council, supported by funds from the Rockefeller Foundation, in connection with its studies of alkaloidal chemistry at the University of Virginia and its pharmacobiologic investigations at the University of Michigan, has endeavored to produce new substances from opium, the addiction liabilities of which are unknown quantities in the human body. The Public Health Service, because of its access to clinical material and its studies of drug addiction incident to the establishment of the U. S. Narcotic Farms, was requested by that committee to determine the addiction liabilities of these new substances when administered to persons afflicted with chronic opium poisoning. Before such studies were undertaken, however, it seemed desirable to develop a technic and method for using these drugs by first-hand observations with morphine and codeine. The two drugs, one of which has pronounced addictive properties and the other questionable potentialities, were prepared by Dr. Lyndon F. Small of the University of Virginia, thus insuring the experimental substances used of being uniform in purity and in chemical composition. This article deals, therefore, with the results of balancing the addiction liability of morphine against that of codeine and is preliminary to further studies dealing with newer substances.

There are two methods pertinent to the study under consideration:

1. Attempt to produce addiction through regular administration of the preparation to be studied over a long period of time.
2. Attempt, through substitution, to maintain a previously established habit by administration of the substance in question.

Employment of the first method would be expensive and time consuming, and it has no particular advantage

over the second method. The rationale for this procedure is found in the following hypothesis: Given valid addiction to morphine, a definite syndrome of abstinence phenomena will set in shortly after its abrupt and complete withdrawal. Hence a substance that can be completely substituted for morphine without permitting the appearance of that syndrome may be addicting in itself even though it is an adequate substitute. If stability can be maintained by the substituted product over a period sufficiently long to rule out abstinence resulting from withdrawal of the morphine, and then can be withdrawn without permitting the appearance of that syndrome, it is probably an adequate non-addicting substitute for morphine; but if abstinence phenomena do set in, that substance is addicting. A substance that cannot be substituted has nothing to offer.

METHODS

Seven white adult males in whom valid addiction to morphine was present on admission were physically and psychically stabilized on four daily hypodermic injections of morphine sulphate over a period of from ten to thirty days. The doses were adjusted to satisfy their respective requirements. Then over a period of

Signs Pertinent to Abstinence

	15. Weight loss

three days effective doses of codeine acid tartrate were substituted, one at a time, for each dose of morphine, so that after the third day no further morphine was administered. It was attempted to adjust the doses of codeine so that the subjects would be unaware of the substitution. Stability was maintained by codeine for the subsequent eight to fourteen days and then it was abruptly and completely withdrawn.

Complete and satisfactory isolation from the remainder of the population was maintained throughout the entire period of observation. That absolute uniformity and control of all conditions and temporal relationships might be assured throughout the entire period of study, observation and supervision were maintained twenty-four hours daily.

The subjects were weighed each morning before breakfast and then blood pressure determinations were made after five minutes of rest in bed. Observations for specific signs of abstinence were made and recorded three times daily. These observations included the presence and degree of the signs listed in the accompanying tabulation, which are pertinent to the abstinence syndrome. The method used in evaluating the degree of abstinence is indicated as mild, moderate, marked and severe.

RESULTS

The case results were quite uniform throughout; but, since the data are too comprehensive to be presented in

detail, the results are given in terms of the degree of abstinence exhibited by the group during the periods of morphine stabilization, transition to codeine, stabilization on codeine, and after abrupt and complete withdrawal of codeine.

Stabilization on morphine was effectively maintained by the administration of four daily injections. The individual requirements ranged from 50 to 150 mg. of morphine sulphate four times daily. None exhibited abstinence after satisfactory adjustment of the individual doses.

During the period of transition to codeine all exhibited mild evidence of abstinence at some time, and three of the subjects became moderately abstinent before the doses of codeine were raised to an adequate size. Because of the low solubility (4 per cent) and the necessarily high doses (240 to 600 mg.) of codeine, it was necessary for the volume constants to be readjusted at this time.

During the eight to fourteen day period of stabilization on codeine, five of the subjects exhibited mild abstinence at some time and two were completely stable throughout. All were thoroughly stable for the majority of this period.

After abrupt and complete withdrawal of codeine, mild evidence of abstinence appeared during the first thirty hours and then suddenly became severe in all cases and continued in its severity until the fourth or fifth day, when recovery set in. The subjects were fit for discharge by the fourteenth day after withdrawal. This picture differs from that of abrupt morphine deprivation only in regard to the delayed onset of severe abstinence manifestations.

All the subjects were aware of the substitution but voiced no objections to it and asked for the substituted product during the acute severity of abstinence. Often the first two injections were followed by localized or generalized flushing and itching, at which time no pulse, respiratory or blood pressure changes were found and no dermographism could be elicited. Otherwise no evidence of toxicity or intolerance was found even though as much as 2.4 Gm. was administered in twenty-four hours. The ratio of daily effective substitution doses of codeine for morphine ranged from 3.8:1 to 8:1; the median ratio was 5:1.

SUMMARY

The habits of seven men thoroughly addicted to morphine were completely and satisfactorily maintained over a period of eight to fourteen days by adequate doses of codeine. The abstinence syndrome that set in subsequent to abrupt and complete withdrawal of the codeine did not differ remarkably from that seen after abrupt morphine deprivation. The median substitution dose of codeine was five times that of morphine.

COMMENT

It is felt that the material presented should be interpreted with due regard to the practical aspects that prevent codeine addiction from becoming prevalent. Codeine is relatively much more expensive than morphine, for narcotic doses are larger. It is inconvenient to administer, because its low solubility and high dosage require large volumes. Codeine is not readily available to the purveyors of illegitimate narcotics.

CONCLUSION

Codeine possesses definite addiction liability.

THE USE OF DILAUDID IN THE PAIN OF CANCER

C. MALONE STROUD, M.D.

ST. LOUIS

The introduction of dilaudid (dihydromorphinone hydrochloride) into this country was attended by much and, in certain instances, most undesirable publicity. Some of the early beliefs concerning its safety have been discredited. As a result, there has been a tendency among certain groups to minimize its usefulness and a failure to use it in many cases in which it would have been of benefit to patients in constant pain. Through the courtesy of the manufacturers¹ I was able to obtain a considerable supply as early as June 1932 and have used it both preoperatively and postoperatively as I had used morphine and codeine. My experience has been chiefly with patients suffering from malignant disease at the Barnard Free Skin and Cancer Hospital.

Pain is an almost inevitable complication of cancer that has progressed beyond the stage of curability. Nearly every medicament known to possess analgesic properties has been used in attempts at its control. It is unnecessary to emphasize the need of an adequate substance for the purpose of giving relief to the many

people who suffer with cancer and who are constantly reminded of their approaching doom by an ever present distress.

An adequate remedy must, first of all, give relief from pain; secondly, it should produce little or no undesirable effects on the patient. Thus far, no drug has been found to supplant opium or some of its derivatives in the control of severe constant pain. Most of the derivatives of opium possess properties that are undesirable, especially if continued use is necessary. Habit formation, undesirable interference with normal gastro-intestinal function, and depression of the central nervous system may be especially mentioned.

The questions that therefore arose when I began the use of dilaudid were:

1. Is dilaudid a satisfactory anodyne for patients with the pain of cancer?
2. Is it less habit forming than morphine and is tolerance more rapidly established?
3. Does it possess the disagreeable side actions of morphine and to the same degree when given in equivalent doses?

In a series of 114 patients suffering with constant pain, the types of malignant tumor were distributed as shown in the table.

From the Barnard Free Skin and Cancer Hospital and the Department of Internal Medicine, Washington University School of Medicine.

Read before the Section on Pharmacology and Therapeutics at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

1. The Biltuber-Knoll Corporation. A preliminary report of the Council on Pharmacy and Chemistry appeared in *THE JOURNAL*, April 1, 1933, and dilaudid was subsequently accepted for admission to New and Nonofficial Remedies.

Although it was not possible to follow all cases uninterruptedly, the special cases selected for detailed report have been observed carefully to their termination and the patients have possessed sufficient intelligence to cooperate in their management.

EFFECTIVENESS OF DILAUDID AS AN ANALGESIC

In every instance in which dilaudid was used, it proved itself an effective anodyne. This is in accord with the observations of many German and a few American clinicians. In the present series it was poorly tolerated in but four cases.

It should be emphasized that continuous relief is desired and not merely the control of the peaks of intense suffering. Most of these patients were seen only after the beginning of constant pain. In order to obtain continuous effect, the method of administration is important. Dilaudid is rather rapidly absorbed and quickly effective if given either by mouth or by hypodermic injection. Absorption is delayed when it is given by rectal suppository and, consequently, the action is more sustained. This is of distinct advantage in the administration of the bedtime dose. Best effects were obtained by the administration of varying amounts about every three hours. It was noted that a single dose given by hypodermic injection or by mouth, except in very severe pain, would give relief for three and one-half hours. The amount given, as well as the time interval, varied, as the tolerance increased and as the pain became more severe. At bedtime the dose was usually doubled and given by suppository. Although dilaudid possessed no hypnotic properties, except in very large doses, patients would usually sleep well for a few nights after it was first administered. After they became accustomed to a degree of relief, it was frequently necessary to administer a sedative or hypnotic, which was usually given at bedtime. In one case, satisfactory hypnosis was difficult to obtain and morphine was resorted to with the desired results.

The analgesic value of dilaudid is well illustrated by the case of E. M., a man, aged 65, who entered the hospital, Nov. 2, 1932. He had a cancer of the right maxillary antrum. He had been treated by cautery and radium. There was considerable destruction of cartilage and the wall of the antrum, as well as a complete destruction of the right eye by a pyogenic infection. His pain was very marked. There had been only partial relief of the pain with morphine, to which he was becoming addicted. In this case, the use of dilaudid was begun on November 3. He was given $\frac{1}{40}$ grain (0.003 Gm.) hypodermically every three hours with more relief than he had previously obtained by $\frac{1}{4}$ grain (0.016 Gm.) of morphine. Occasionally, this dosage was augmented at night by a suppository containing $\frac{1}{12}$ grain (0.005 Gm.) of dilaudid and sometimes it was necessary to give a barbiturate as a hypnotic. The patient gradually became weaker and died, Jan. 9, 1933. Presumably unconsciousness, which came on January 8, was caused by an extension of the tumor and infectious process to the brain.

In the case of H. B., a woman, aged 34, a troublesome cough, as well as a marked constant pain of terminal carcinoma, was controlled. She was admitted to the clinic, June 24, 1932. There was a history of productive cough, uterine bleeding and a considerable loss of weight. She was found to have a cancer of the cervix, syphilis and pulmonary tuberculosis. She was given roentgen therapy, which resulted in a cessation of the menorrhagia. On account of the increase in cough and lower abdominal pain, dilaudid was started, Sept. 6, 1932. She was given a dosage of $\frac{1}{48}$ grain (0.001 Gm.) every three hours and felt much better, with relief of the cough and pain. She had a total of 4,950 milligram hours of radium, the last treatment being given October 9. She died, October 28.

The value of dilaudid as a cough remedy in cases of proved lung metastases has been noted many times.

This property of the drug played an important part in the comfort of G. G., a man, aged 53, who was first admitted to the clinic, Feb. 18, 1931. A diagnosis of osteogenic sarcoma of the left leg was made and the patient was advised to have his leg amputated but refused. He was treated by the use of high voltage roentgen therapy, with some relief of the pain and a diminution in the size of the tumor mass. In January 1932 he came back to the hospital, complaining of pain and increase in the size of the tumor. At that time, amputation of his left leg was done, after it was noted that there were no obvious metastases.

In April 1933 he appeared in the clinic, complaining of a troublesome cough, productive of a blood streaked sputum, with considerable pain in his chest. He was started May 5, 1933, on dilaudid, $\frac{1}{48}$ grain (0.001 Gm.) by mouth every three hours. He gradually grew weaker but suffered no pain and very little cough. Edema of his leg appeared and he was digitalized and placed on iron, by mouth. He was last seen in our clinic, Sept. 26, 1933. He died, Oct. 9, 1933.

In this case, relief of constant pain definitely prolonged useful activity. Dilaudid when given by mouth was usually given in aromatic elixir.

HABIT FORMATION AND TOLERANCE

It has been stated that dilaudid is less habit forming than morphine. Eddy's report² cited several references in the German literature of cases of addiction. Since it is desirable, even in cancer work, to use a non-habit forming drug, we were interested in observing this property. Euphoria was noted only once with a dose as small as $\frac{1}{32}$ grain (0.002 Gm.) and very rarely with larger doses. Several patients were able to take dilaudid for twelve weeks or more, and when they no longer needed it gave it up without craving. It is apropos to relate the history of a patient with cancer, who, because of treatment, was able to omit dilaudid without symptoms of craving for three months:

H. F., a white man, aged 48, entered the clinic, Oct. 5, 1932, complaining of painful swelling of the neck. Following the opening of an abscess some ten months before, a small round mass had appeared. In about four months, lymph nodes of the neck began to enlarge, followed shortly by blindness of the left eye. Biopsy of one of the enlarged cervical nodes revealed cancer. He entered the hospital, Nov. 9, 1932, complaining of severe pain. He also had a large tumor mass, almost filling the nasopharynx. For the next five weeks his pain was controlled by the administration of $\frac{1}{32}$ grain (0.002 Gm.) of dilaudid by mouth every three hours. At the end of this period his pain had been sufficiently relieved by x-rays so that medication for its control was no longer necessary. The drug was stopped and was not given for three months. In March it was necessary to resume dilaudid, as roentgen therapy no longer relieved the pressure from the tumor mass sufficiently to control the pain. Dilaudid in this case controlled the pain quite well but the patient lived beyond our expectations and it was necessary to increase the dosage to a marked degree. At one time before his death there was a period of a few days when he received 1 grain (0.065 Gm.) of dilaudid orally every three hours. Constipation, which had been pronounced before beginning dilaudid, was not materially increased.

While few of our patients were ever taken off dilaudid after it was once begun, there were many cases in which the symptoms of craving were not notable.

In several cases, dilaudid was given after morphine had been used for varying periods of time. In every case the substitution was welcomed except in two cases

2. Eddy, Nathan B.: Dilaudid (Dihydromorphinone Hydrochloride). J. A. M. A. 100:1032 (April 1) 1933.

in which there had been a history of morphine addiction before the onset of malignancy. One of these patients was a physician who was suffering from carcinoma of the antrum and who had been treated with large amounts of morphine. He was given dilauidid in doses approximately equivalent to the amount of morphine that he had been taking. A ten day trial of dilauidid failed to give him the subjective relief previously afforded by morphine, and his craving for morphine was not satisfied by dilauidid. Psychic disturbances prevented accurate observation of the analgesic property of the drug in this case.

Through the courtesy of Dr. Julius Jensen, I was permitted to see a patient who, after a relatively short use of dilauidid, had developed a decided craving for the drug. He would become nervous and fidgety and would cry unless either morphine or dilauidid was administered promptly at the expected interval. Another patient, an elderly woman with marked arthritis and symptoms of senile dementia, developed a profound liking for the drug after three weeks' use.

While it was difficult to estimate the rapidity at which tolerance was established, on account of the increase in pain, there were a few cases that seemed to require a more rapid increase of dosage than others.

This was especially noted in the case of W. D., a man, aged 56, who came under observation, Jan. 22, 1933. He was operated on and a gastro-enterostomy was done for relief of pyloric obstruction due to cancer, February 15. After operation he gained weight and resumed his work until the early part of May, when he developed severe pains in the stomach. He was then started on $\frac{1}{160}$ grain (0.00065 Gm.) of dilauidid by mouth every three hours. He did not obtain relief of pain until after the dosage was increased to $\frac{1}{48}$ grain (0.001 Gm.). Finally, $\frac{1}{24}$ grain (0.0027 Gm.) gave relief for about two hours, and $\frac{1}{6}$ grain (0.01 Gm.) by suppository at night gave relief for several hours but did not make him sleep. The patient was then given amylal and chloral, which were poorly borne by the stomach. Finally, on August 4, he was placed on morphine sulphate $\frac{1}{4}$ grain (0.016 Gm.) orally every three hours, which caused him to sleep more than formerly. He was practically moribund until his death, Sept. 15, 1933.

In several cases habituation was suspected, but on account of the constant pain the drug was not withheld and therefore its existence was not definitely determined. It was not considered that tolerance and habit formation were coincidental.

UNTOWARD SIDE ACTIONS

Undesirable side effects were not evident in most cases. Nausea, even in malignant conditions of the intestinal tract, was noted but four times in this series. These patients also had nausea from morphine. Two of them were not nauseated by codeine. As a rule, however, many who had gastro-intestinal disturbances from morphine tolerated dilauidid without this undesirable consequence.

An example of the usual response is found in the history of P. L., a woman, aged 27, who first came under our observation in July 1932. A diagnosis of carcinoma of the cervix was made and a hysterectomy was done at the University of Michigan, Feb. 21, 1932. In April 1932 she was given radium to the affected region. Shortly after this she began to have severe pain in the lower abdominal wall. The pain increased and she was admitted to the Barnard Free Skin and Cancer Hospital, June 3, when it was noted that she had considerable tenderness in the right lower part of the abdomen. The abdominal incision was stony hard. The impression was that the patient had a cervical recurrence with implantation into

the abdominal scar. She required morphine for relief of pain from June 3 to June 20. She was receiving $\frac{1}{2}$ grain (0.02 Gm.) of morphine sulphate hypodermically every three hours, and occasionally more frequent administration was necessary. She obtained considerable relief from pain but tolerated morphine very poorly, having almost constant nausea and loss of appetite.

She was given a suppository containing $\frac{1}{10}$ grain (0.006 Gm.) of dilauidid night and morning, with absolute relief from pain, as well as relief from nausea and a consequent improvement in appetite. After roentgen therapy she gained some weight and was discharged from the hospital.

On returning to her family physician she was unable to obtain dilauidid and it was learned that morphine, which she took again, was tolerated poorly as before. She was then given dilauidid, $\frac{1}{8}$ grain (0.008 Gm.) in suppositories every eight hours with considerable relief until her death, Dec. 20, 1932.

One of the patients who could not tolerate dilauidid was F. B., a man, aged 55, observed in the clinic from September 1931 until Dec. 29, 1933. He had a carcinoma of the left buccal mucous membrane, with metastases to the submaxillary nodes. Oct. 5, 1933, he was put on dilauidid. He experienced considerable relief from pain for two days, when it was noted that the medicine caused nausea. In spite of the fact that nausea was noted even when dilauidid was disguised, he obtained relief from pain. In this case dilauidid was administered by mouth only and not hypodermically or by suppository.

Constipation was never a troublesome factor. Many patients, especially those able to eat properly, experienced no costive symptoms. Constipation was present in most patients on soft or semisolid diets before dilauidid was given and was thought to be slightly increased in some instances.

While Krehl,³ Hemmerling,⁴ Trautmann⁵ and Winternitz⁶ reported marked effect on the respiratory center, this was at no time objectionable in the management of our 114 cases. Dreyer,⁷ in a series of patients at Barnes Hospital, observed a marked slowing of respiratory rate in one case following a dose of $\frac{1}{32}$ grain (0.002 Gm.).

Despite the fact that tolerance and habituation to the drug are undoubtedly more common than physicians were formerly led to believe, deterioration of character was much less marked than had been noted with morphine. Most patients approached death with less anxiety and, consequently, with a better morale than had been noted before the use of dilauidid.

CONCLUSIONS

1. Dilauidid is an efficient analgesic in the control of constant pain. It is more helpful in cancer than any other opiate I have used.

2. In order to obtain continuous relief of constant pain, the method of administration is important. The doses should be administered with sufficient frequency to permit continuous effect.

3. Although in the type of case that I observed the detection of habituation was difficult, I believe that dilauidid is less habit forming than morphine. There was less deterioration of character and better morale in patients who were treated with dilauidid than in patients treated with other drugs.

4. The untoward side effects were less troublesome than those of other opiates.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. EDMUNDS, EDDY AND SMALL,
DR. HIMMELSBACH AND DR. STROUD

DR. TORALD SOLLMANN, Cleveland: The work reported by Drs. Edmunds, Eddy and Small is a notable attempt to develop a new drug. No one can predict whether it will be entirely successful, but already the work has added something material to existing knowledge. Even if it had not done so, it would be worth while as an illustration of how such problems should be approached. The outlook of improving on morphine in one way or another is good. There has long been one useful modification in codeine, and the dilaudid observations as reported by Dr. Stroud are also promising. It must not be forgotten, however, that diacetylmorphine seemed a panacea for a year or two. Dr. Himmelsbach's interesting work in a sense grew out of the collaboration that led to the investigation that was described by Dr. Edmunds and his co-authors. Addiction tendency is difficult to test. Codeine is a noted illustration: The codeine habit is a rarity at the present time and the use of snuff is a rarity, but it does not follow that snuff cannot form a habit. To the contrary, tobacco snuffing was universal a hundred years ago. Similar considerations may very well apply to codeine. There are many factors that enter into the production or the actual employment of a habit-producing drug. Dr. Himmelsbach has sketched these; side effects, costs, fashions, all enter in. A drug might be a very effective addiction drug and never be used because it did not happen to become commonly known. One must therefore attempt to study the habit-producing ability of a drug by objective methods and not merely by statistics, which might change completely almost overnight. The method that Dr. Himmelsbach reports seems to have worked out that problem successfully. It has the important advantages, first, that it doesn't make any victims and, second, that it uses patients who are known to be susceptible to drug habits; theoretically all are, but practically there is a great difference. With this method, I feel convinced that one is able to say certainly whether a drug is capable or incapable of producing a habit, without waiting for a tragic clinical demonstration.

DR. NORMAN A. DAVID, Morgantown, W. Va.: I should like to point out the similarity between dilaudid and the new compounds such as the desoxymorphines, which Dr. Edmunds and his co-workers believe will be most useful practically. These two compounds differ only that in dilaudid the alcoholic hydroxyl (of morphine) has been replaced by oxygen, while hydrogen has been substituted in the desoxymorphines. I should like to ask whether it is possible that the oxygen containing derivatives may prove pharmacologically more effective than the hydrogenated ones. Usually it is thought that oxygenated compounds are more active, at least chemically, than those with hydrogen. Dr. Himmelsbach answers the clinician's query as to whether or not codeine is habit forming. However, a question or two arises. Could it be possible that when codeine is abruptly substituted in the morphine addict this closely related opiate (codeine) in some unknown way delays the excretion of morphine that otherwise would take place? Then, when codeine is acutely withdrawn after the short period of eighteen to twenty days of substitution, could the resultant abstinence symptoms be due in part to the eventual excretion of this residual amount of morphine? For the past year I have been making tests of dilaudid in comparison with morphine in a study of their effects on the basal metabolism, tactile discrimination and other body functions. I found that the usual 2 mg. ($\frac{1}{32}$ grain) dose of dilaudid given subcutaneously produced slightly greater loss of tactile discrimination and lowering of the metabolic rate than 16 mg. ($\frac{1}{4}$ grain) of morphine sulphate. Consequently, I am interested in the statement of Dr. Stroud that dilaudid in small doses has little or no hypnotic effect. Nor have I been as fortunate as Dr. Stroud in obtaining a relative freedom from side actions in patients given dilaudid, although compared with morphine the incidence was appreciably less. There is no doubt in my mind that dilaudid offers definite improvement as an opiate over morphine. However, I await anxiously for the clinical reports on the trial of the new compounds developed by Drs. Edmunds, Eddy and Small.

DR. HAROLD S. DIEHL, Minneapolis: The possibilities of codeine addiction interest me because of the extent to which my associates and I have been using codeine with papaverine in the treatment of acute coryza. We have used $\frac{1}{4}$ grain (16 mg.) of codeine with $\frac{1}{4}$ grain (16 mg.) of papaverine, in an average dosage of five capsules a day over a two-day or occasionally three-day period. I should like to ask Dr. Himmelsbach whether he thinks there is any possibility of addiction to codeine used in this dosage over such a period of time.

DR. NATHAN B. EDDY, Ann Arbor, Mich.: I was especially interested in Dr. Stroud's remarks about the possibility of addiction. The evaluation of addiction experimentally, that is, in animals, is exceedingly difficult. Nevertheless, we have made some attempts in that direction and have administered dilaudid, along with other substances, to different species of animals, with the intent of determining whether or not these substances will produce tolerance, whether or not the presence of any abstinence or withdrawal symptoms can be determined after the substances have been given over a prolonged period. There is no question in our minds that experimentally it can be shown that the animals become tolerant to dilaudid as they become tolerant to morphine, except that perhaps the tolerance develops a little more slowly. Also, there is no question in our minds that in monkeys abstinence symptoms will develop if dilaudid is given over a sufficiently long period of time. That is especially noteworthy in connection with observations previously reported on the administration of different opiates to monkeys. Monkeys develop abstinence symptoms after they have had morphine; they will also develop abstinence symptoms after they have had dilaudid. They do not develop those quite as quickly as they do after morphine. The effective ratios of the different effects of dilaudid to the same effects of morphine vary. On the whole, our impression is that the effective ratios of dilaudid to morphine for therapeutic effects are very close to the ratios of the toxic doses, so that the margin of safety with dilaudid is little different from the margin of safety with morphine. Dr. David raised the question of the relative value of the substitution of the hydroxyl by oxygen or by hydrogen. So far as minimal effective dose is concerned, the substitution by hydrogen is very much more effective than substitution by oxygen. The ratios of effective doses when one substitutes by hydrogen, as in dihydrosesoxymorphine-D, are very much greater than when one substitutes by oxygen, as in dilaudid. The margin of safety when one substitutes by hydrogen is very much greater than when one substitutes by oxygen. The duration of effect, on the other hand, is probably somewhat shorter when hydrogen is the element substituted. Up to the present time, we have not been able to develop abstinence symptoms with dihydrosesoxymorphine-D. The animals do become tolerant to this new substance.

DR. C. K. HIMMELSBACH, Fort Leavenworth, Kan.: In reply to Dr. Diehl's question, Drs. Shibley and Spies pointed out in their paper that the common cold rarely lasts more than ten days and Dr. Diehl followed it with his statement that treatment with codeine and papaverine materially shortened this period. I doubt, except in extremely susceptible cases, that the codeine and papaverine combination as prescribed by Dr. Diehl would result in conference of addiction. However, in individuals particularly susceptible to addiction the euphoric effects of the drug have resulted from a single dose. Codeine possesses minimal euphoric properties compared to morphine. In reply to Dr. David, I may state that it has never been shown that codeine inhibits the excretion of any drug. There is no reason to suppose that it would inhibit the excretion of morphine. It is well known that the excretion of morphine is essentially the same in the nontolerant and the completely tolerant organism. The two weeks period of complete substitution of codeine would undoubtedly rule out retarded excretion of morphine.

DR. C. MALONE STROUD, St. Louis: I should like to emphasize the need of giving continuous relief, if possible, to patients who are in constant pain. Before the advent of dilaudid, an attempt was made to give continuous relief to patients with painful carcinomas by administration of codeine and morphine. The by-effects of these drugs almost invariably became distressful in prolonged cases. Dilaudid gave continuous relief, in most instances, without producing troublesome symptoms.

THE BIOLOGIC EFFECTS OF THYMUS
EXTRACT (HANSON)ACCRUING ACCELERATION IN GROWTH AND DEVELOP-
MENT IN SUCCESSIVE GENERATIONS OF RATS
UNDER CONTINUOUS TREATMENT WITH
THYMUS EXTRACT

PHILADELPHIA

In this investigation we believe that we have learned something suggestive concerning the thymus gland and what is equally important, perhaps, we have evolved a novel procedure for the study of this and possibly other endocrine products. Following the continuous administration of thymus extract to successive generations of parents, marked acceleration in the rate of growth and development has been observed during the early life of the offspring, particularly of the third and later generations. Thus the rate of development encountered in the fifth generation of young rats born of four generations of thymus treated forebears is almost beyond belief.

METHODS OF EXPERIMENTAL PROCEDURE

A colony of twelve white rats was secured from the Wistar Institute, June 16, 1933. These were divided into test and control groups. The test animals have been subjected to date to the intraperitoneal injection of 1 cc. of thymus extract (Hanson) daily, even during the periods of pregnancy and lactation. Litter mates born to these rats have been mated in pairs and these have likewise been subjected prepubertally or after they have reached maturity to intraperitoneal injection of thymus extract. Each succeeding generation has likewise been so treated and the effects on parents and on the offspring noted. Thus, original test animals of the first generation (F_0) have undergone continuous treatment since June 16, 1933, the F_1 generation since Sept. 10, 1933, the F_2 generation since Sept. 25, 1933, the F_3 generation since Jan. 19, 1934, and the F_4 generation since April 15, 1934. In the young, treatment has usually been begun from the sixteenth to the twentieth day after birth in the prepubertal group and from the fortieth to the sixtieth day in the mature group. Numerous controls have been employed. At the present time we have reached the fifth generation of thymus treated rats and have between 300 and 400 rats in our colony.¹

The rats are confined in pairs in circular mesh wire cages the floor of which is covered with excelsior. Cups for food and water are attached to the wall of the cages. All rats used were placed on a diet containing the following ingredients to each 100 parts: rolled oats 15, hominy 60, dried meat scraps 14, Dryco 10, sodium chloride 1. To 100 Gm. was added cod liver oil in the

amount of 1.25 cc. Additional nutriment consisted of diluted milk daily and greens twice a week. Later orange juice was added to the diet at the suggestion of Dr. H. H. Donaldson. The quantity of food was not fixed. They were given daily more than ample for their needs, the food remaining at the end of twenty-four hours being discarded. Water was ingested ad libitum.

All twelve rats originally used were of Wistar strain and of known age and known parentage. Eight of these were divided into mature and prepubertal test and control pairs, each pair consisting of litter mates. The remaining four mature animals were segregated according to sex. One male and one female were injected and the others used as controls.

Up to April 16, over a period of ten months, we have followed two pairs of thymus injected rats in the F_0 generation for ten and six months, respectively. From their offspring, test and control pairs have been mated and the same procedure has been followed in each succeeding generation. Our experiments can be divided into three groups: (1) those pertaining to continuous treatment, daily intraperitoneal injections of rats carried on in succeeding generations, (2) those in which treatment (daily injections) was interrupted for one or more generations, and (3) feeding experiments

in which the thymus extract was administered by mouth. In group 1, three series of animals were studied, 1A, the original group of rats subjected to injection of thymus extract (Hanson) since June 16, 1933, 1B, a second series of Wistar rats subjected to an identical form of treatment, to act as a control to the first group (treatment started on Oct. 5, 1933), and 1C, a group of rats subjected to similar treatment with a new preparation of thymus extract (Hanson) supplied from another source.

THE NATURE OF THE THYMUS EXTRACT USED

The extract used in these experiments was prepared by Hanson² in 1930 briefly as follows: The thymus glands from 2 to 6 weeks old calves were extracted in 0.5 per cent hydrochloric acid solution with the aid of heat. This extraction differs from the extraction from parathyroids by Hanson simply in the degree of acidity used in its preparation. This preparation is extremely stable and is entirely potent and satisfactory for injection in rats even after being kept at room temperature from two and one-half to four years. The extract was golden yellow and resembled bouillon in taste and smell. It has a pH of about 5.0 and is nontoxic in relatively large doses and nonirritating locally on injection.

Chemical analysis of this extract made at three years yielded the results given in table 1.

The strength of the extract used represented 0.6 Gm. of raw calf thymus to 1 cc.

BIOLOGIC DATA ON NORMAL AND
CONTROL RATS

Controls.—Our controls are of two kinds: (1) the published data obtained in the study of rats at the Wistar Institute, summarized in *The Rat*, by Dr. H. H. Donaldson, and (2) three pairs of Wistar bred rats and their descendants paired as litter mates and carried along in our laboratory on the same food and under the same conditions as the thymus treated test rats.

The biologic data on all our control animals conforms in general with those published from the Wistar Institute. However, our rats were subjected to daily intraperitoneal injections of salt solution containing 20 per cent of glycerin over a period of several months. As this has been found to be without effect, it has been discontinued. At the present time a control series is being run in which injections of an extract made by Hanson from lymphatic glands are being administered.

The comparison of our figures with those of Dr. Donaldson is shown in table 2.

Thus it is evident that our control animals evidence somewhat earlier gonadal development and maturity than the Wistar rats. In addition it should be stated

that the weight curves of the two series of animals are identical up to twenty days, after which the weight of our animals lagged somewhat as compared with the Wistar strain.

RESULTS OF CONTINUOUS TREATMENT OF SUCCESSIVE GENERATIONS OF RATS—SERIES 1A

As the result of continuous treatment of successive generations of rats with 1 cc. intraperitoneal injections daily the test male animals became somewhat heavier than their controls, the females becoming heavier after mating. The test animals seemed to breed more frequently and had larger litters of heavier average weight. Thus the mature test pair cast nine litters of seventy-eight plus animals and the mature control pair cast three litters of eight animals by March 13, 1934, at which time the control mother died. The prepubertal test pair cast four litters of twenty-seven plus animals, the female dying during labor, Nov. 14, 1933, while the prepubertal control pair cast two litters of ten plus animals for a corresponding period.

Growth and Development of the Second Generation Rats (F_1).—In all, ninety-three rats were born in thirteen litters to two pairs of test animals of the first generation (F_0) under treatment. The biologic data indicate rapid breeding on the part of the parents, an average period between casting of litters of 28.5 days

for the test animals as compared with 42.5 days for the controls. The average litter was composed of more than seven rats, as compared with less than five per litter for the controls. The animals at birth were approximately 10 per cent heavier than the controls. Seventy-nine per cent of the offspring of the test animals survived, as compared with 37.8 per cent of the offspring of the controls.

No precocity was observed in this generation in the earlier litters relative to the opening of the ears, the eruption of the teeth, the development of fur, the opening of the eyes. However, gonadal development and maturity were somewhat earlier than normal. In the later litters, definite evidence of precocity began to appear. Thus, in the tenth litter (cast after April 16) the animals at birth were considerably larger than normal. The animals were covered with fur and opened their eyes by the tenth day. The tenth litter also evidenced a considerable increase in the growth curve at 20 days, the test rats weighing 46 Gm. as compared with 28 Gm. for the controls.

In summarizing the results of treatment in the second generation (F_1), it might be said that treatment of the parents with thymus extract (Hanson) apparently results in an increased number of litters, an increase in the size of the litters, an increased birth weight, and a decreased infant mortality compared with our controls. In later litters born to such parents, evidences of precocity appear; i. e., increased birth weight, earlier eruption of the teeth, appearance of fur, opening of the eyes, descent of the testes and opening of the vagina.

Growth and Development of Third Generation Rats (F_2).—In test animals of this generation, i. e., animals born of two generations of rats treated with thymus extract, the rate of growth and development was astonishing. In all, 134 rats were born in seventeen litters to five pairs of second generation (F_1) rats under treatment with thymus extract. The interval between gestations was 39.6 days as compared with 42.5 days for the controls. An average of 7.8 rats per litter was cast as compared with 4.9 in the control litters. The average birth weight was 5 Gm. for the test animals as compared with 5.3 Gm. for the controls. Seventy-six per cent of the test young survived as compared with 37.8 per cent of the controls. The ears opened on the first day. The incisors erupted from the first to the second day. The animals were covered with fur from the third to the sixth day. The testes descended from the fifth to the thirteenth day. The vagina opened from the twenty-third to the thirty-second day.

Rate of Growth and Development in the Fourth Generation (F_3).—The fourth generation consists in all of 100 animals born in seventeen litters to eight pairs of rats treated with thymus extract. The parents, grandparents and great grandparents had all received injections of thymus extract (Hanson). The interval between casting litters averaged thirty-four days as contrasted with a period of 42.5 days in the controls. The average litter consisted of six animals with a birth weight of 5.3 Gm. as compared with an average control litter of 4.9 animals with an average birth weight of 4.6 Gm. Sixty-nine per cent of the young survived as compared with 37.8 per cent surviving in the control series. The ears opened within twenty-four hours in every rat. The incisors erupted within twenty-four hours. Fur appeared between the second and fourth days of life. The eyes opened on the fourth day. The testes descended from the fifth to the twelfth day and

the vagina opened from the twenty-first to the twenty-seventh day.

Rate of Growth and Development of Fifth Generation Rats (F_4).—The fifth generation consisted of twenty-one rats born to one pair, nine in the first litter and twelve in the second litter. All nine of the first litter died, apparently from lack of the mother's milk. All twelve of the second litter survived. The average birth weight in these animals was 5.6 Gm. as compared with 4.6 Gm. in the controls. The ears were open at the first inspection and the incisors likewise had erupted. These animals developed hair between the second and third days, the pelt being perfect within seventy-two hours. The animals opened their eyes between two and one-half and three days. The testes descended on the fourth day and the vagina opened on the eighteenth day. So alert and mature were these animals on the third day that one pair was weaned and has never been in the cage with the mother or with any other rats since the third day. These animals found their own water, milk and food supply and have surpassed all their litter mates in weight by 2 Gm. each. On the twenty-fifth day these animals weighed 94 Gm. as compared with 37 Gm. for controls of the same age, practically 150 per cent more.

RESULTS IN SECOND SERIES OF RATS UNDER CONTINUOUS TREATMENT—SERIES 1B

So incredible seemed the results of thymus injection in our first series of rats that we felt confirmation was imperative. A conference was held with Dr. H. H. Donaldson as soon as the precocity of our third generation test rats was noted. At this conference it was decided to continue treatment of the original group until ten litters could be studied and also at the same time to repeat our experiments, starting with a new series of rats.

Accordingly two pairs of controls were started on daily intraperitoneal injections of 1 cc. of thymus extract (Hanson), Oct. 5, 1933. In this series we find complete confirmation of our earlier results. In the second generation the period between casting of litters is short, varying from twenty-two to twenty-six days. Four litters of the third generation were born between Feb. 22 and May 6, 1934. The average litter was seven and the birth weight nearly 5 Gm. The ears opened within two days. The animals were covered with fur in from three to five days and the eyes opened in from four to five days. At birth these rats appeared normal. They flourished in early life, then faltered and wasted away, apparently from lack of the mother's milk. Two rats of the fourth litter were removed from the mother and placed with a "wetnurse" control mother. They evidenced the same precocity, the testes descending on the fifth day and the vagina opening on the twenty-sixth day.

Thus a repetition of our earlier experiments yielded complete confirmation of our earlier results in striking precocity, in the rate of growth and development appearing in the young of the third generation.

RESULTS IN A SERIES OF RATS UNDER CONTINUOUS TREATMENT WITH THYMUS EXTRACT FROM ANOTHER SOURCE—SERIES 1C

All the results so far described have been obtained from the use of the original preparation of thymus extract sent to us by Hanson. As has already been stated, this extract was prepared in 1930 and hence has stood for some two and one-half to four years prior

to being used. The new preparation of thymus extract was received on Jan. 6, 1934. It was administered intraperitoneally 1 cc. daily as in the other studies recorded. It has been continued over a period of from four to six months.

Six rats of the first series born of old thymus injected rats and hence representing the second generation or F_1 were placed under treatment. If this extract had been as effective as the old, the animals born to these three pairs of rats should have evidenced the same degree of precocity as our third generation (F_2) rats treated with the original thymus extract. In no instance did the offspring conform to those of our third generation (F_2) under treatment with the original thymus extract. Hence we decided that this extract was lacking in potency.

The same type of experiment was carried out with rats of the third generation (F_2) under treatment with old thymus extract. Their offspring likewise failed to conform with the expected precocity. From these experiments, which will be recorded in detail later, it

Fig. 1.—At right, control rat 14 days old; at left, third generation thymus test rat 15 days old.

can be seen that the effect of the new thymus extract administered by injection is slight or perhaps lacking. During the six months of treatment, the animals of the second and third generations injected with the new

* The low numbers usually relate to late litters in the generation and the high numbers to the first litters born.

thymus extract failed to manifest the acceleration of growth and development that should have accrued had the animals continued on injections of the original thymus extract.

The salient features relative to the accruing acceleration in the rate of development in succeeding generations can be easily appreciated from the data in table 3.

EFFECTS ON THE OFFSPRING OF RATS OF THE WITHDRAWAL OF TREATMENT WITH THYMUS EXTRACT (HANSON)

An effort has been made to determine the effect of omitting treatment through one or more generations. It was thought that it would be of interest to know whether this effect persisted after cessation of treatment, and if so for what period of time. In this connection we have observed many groups of animals, totaling over 200.

This experiment is difficult of presentation. However, details are available and will be published shortly. The results of interruption of treatment can be stated briefly. Cessation of treatment through one generation usually results in the entire disappearance of precocity. This does not hold in all instances, particularly for the first litter born after cessation of treatment of the parents. Here mild precocity may appear, provided interruption of treatment has not been of long duration.

Fig. 2.—At right, control rat 7 days old; at left, fourth generation thymus test rat, 6 days old, the eyes open.

In the second litter normality is reestablished almost invariably, while the third litter conforms to normal in every instance.

EFFECTS OF FEEDING THYMUS EXTRACT

An effort has been made to determine whether or not thymus extract is effective when administered by mouth. In order to determine its effectiveness, it has been administered to four pairs of rats, all of which were born to animals having received old thymus extract by injection. In other words, these four pairs of animals represent second generation (F_1) rats under thymus treatment. These pairs, had treatment with the old extract been continued by injection, would have shown in all probability the marked precocity already recorded in our third generation (F_2) thymus treated rats.

From 8 to 10 cc. of the new thymus extract has been mixed daily with the food of each pair of rats over a period of four months. The first pair of rats cast one litter, consisting of six animals, all of which survived. They showed an average birth weight of 5.3 Gm. Their ears opened on the second day, the teeth erupted from the fourth to the sixth day, hair appeared from the

ninth to the twelfth day, the eyes opened from the twelfth to the thirteenth day; the testes descended on the twenty-second to the twenty-sixth day, and the vagina opened on the forty-sixth day.

The second pair had one litter of six, all of which survived. Their average birth weight was 5.2 Gm. Their ears opened on the second day, the teeth erupted on the eighth day, hair appeared from the tenth to the twelfth day, the eyes opened on the twelfth day; the testes descended on the twenty-ninth day, and the vagina opened on the fortieth day.

The third pair cast one litter of twelve animals, all of which survived. Their average birth weight was well over 6.9 Gm. The ears opened on the second day, the teeth erupted on the eighth and tenth days, hair appeared from the tenth to the twelfth day, the eyes opened from the twelfth to the thirteenth day; the testes descended on the twenty-second and twenty-third days, and the vagina opened on the thirty-sixth and fortieth days. No marked precocity was seen in the fourth litter.

It is apparent in these studies that the new thymus extract when fed by mouth does not induce the precocity that would have been expected had these animals received the old thymus extract intraperitoneally. From these results we are convinced that the new thymus extract when administered by mouth has little or no effect. Unfortunately this experiment was not attempted with old thymus. The new thymus extract used intraperitoneally was, as has already been indicated, relatively ineffective. Hence we feel that from these experiments the evidence is not at all convincing and in order to determine whether or not thymus extract is effective by mouth we feel that a similar experiment must be carried out on a series of rats with an extract known to be potent when it is administered intraperitoneally.

ACTIVITY AND BEHAVIORISM OF RATS UNDER THE INFLUENCE OF THYMUS EXTRACT (HANSON)

The psychic precocity is as striking as the physical in the thymus treated strain of rats. Thus, fifth generation (F_4) test animals move about the cage at 3 days of age and appear almost as capable and alert as normal rats of 16 to 20 days of age. These animals will climb out of a wire net enclosure from 3 to 4 inches high and manifest all the activities of normal animals four or five times their age. Weaning is possible at 3 days of age, the little rats finding their own supply of water, milk and food. They nest, burrowing under the excelsior, and find a resting place and have no need of further care from the parents. Animals weaned as early as the third day have fared as well as or better than their litter mates left with their parents.

The thymus treated animals appear to be healthy, contented and docile. Their actions asleep or awake resemble those of normal controls in every way. They do not resent the needle to any great extent, apparently suffering no pain or distress following the injection of thymus extract. We have wondered at times whether the chlorbutanol used as a preservative in this extract might in any way account for the docility observed.

White rats swim instinctively. The young rats swim as soon as their eyes open and they are covered with fur. Thus, our third generation rats swam at the age of 6 and 7 days, our fourth generation rats at 4 and 5 days, and our fifth generation rats at 3 and 4 days. None of these animals would enter water voluntarily,

but when placed in water appear momentarily at a loss and then swim to the nearest ledge. If the water is not too deep, they stand on their hind legs and attempt to spring to safety. Control rats cannot swim until after the eyes open; i. e., until from 14 to 16 days of age.

It should be clearly understood that the effect of thymus extract is confined largely to the rate of growth and development in the young. After sixty days the weight curves of control and test animals approach each other. Eventually in the fully mature animals little difference in size is apparent. Giants do not develop. Thymus is concerned chiefly with the young. To date we have seen no evidence that the life of rats is shortened by thymus, but our experiments have extended only over a year.

Fig. 3.—At left, control rat 5 days old; at right, thymus treated rat of fifth generation, 3 days old, the eyes open.

TOXICITY

Large doses of thymus extract (Hanson) are toxic. The administration of 5 cc. intraperitoneally results shortly in temporary incapacitation or collapse. Electrocardiac tracings made in the Heart Station of the Philadelphia General Hospital in conjunction with Dr. Thomas McMillan, head of the department, and Dr. Samuel Bellet reveal interference in conduction and the development of auriculoventricular block. Larger doses kill by complete heart block.

THE WEIGHT CURVES OF RATS UNDER THE INFLUENCE OF THYMUS EXTRACT

Weight curves of rats under the influence of thymus extract reveal a markedly accruing acceleration in weights in rats of the third, fourth and fifth generations. This is shown in the accompanying chart, in which C represents the controls, F_1 the second generation, F_2 the third, F_3 the fourth and F_4 the fifth generation under the effects of excess of thymus. The shaded areas represent the growth of more than 2,000 Wistar rats between Oct. 7, 1933, and Jan. 30, 1934. These curves are based on three litters of controls (eighteen animals), five litters of the F_1 generation (fifty-two animals), four litters of the F_2 generation (thirty-one animals), two litters of the F_3 generation (eighteen animals) and three litters of the F_4 generation (sixteen animals). All our animals were on a stock diet and were never mated later than 60 days, whereas the rats of the Wistar Institute were on a varied breeders' diet and were usually not mated earlier than 90 days.

A study of these curves indicates deficiency in growth in our control rats after the twentieth day and a striking and increasing acceleration in the weight of our thymus treated animals of the third, fourth and fifth generations. Our fifth generation rats at all times from the fourth to the fortieth day weighed more than double the control rats and at all times up to 30 days of age

outweighed the rats of the Wistar Institute. Between the third and twentieth days our fifth generation rats exceeded the Wistar rats in weight by more than 100 per cent.

After the sixtieth day these curves tend to come together. This will be presented in a later publication.

SUMMARY

1. The preparation of thymus extract (Hanson) forwarded to us by Hanson is a potent thymus extract, derived from the thymus of young calves.

2. Thymus extract (Hanson) seems to increase the weight and growth of prepubertal and mature male rats and in mated mature female rats.

3. Thymus extract (Hanson) administered to the new-born exerts but little effect on growth and development, although earlier opening of the eyes has been noted at times.

4. Thymus extract (Hanson) administered intraperitoneally to parent rats seems to increase the number and size of the litters and the birth weight of the offspring.

5. The most striking biologic effects of thymus extract (Hanson) are obtained and are most evident in the offspring following continuous treatment by intraperitoneal injection of successive generations of rats.

6. The third generation test animals, i. e., rats born of thymus treated parents and grandparents, are larger at birth and evidence striking precocity in growth and development, interpreted by early eruption of teeth, appearance of fur, opening of the eyes, descent of the testes and opening of the vagina.

7. Successive generations of rats born to thymus injected parents evidence accruing acceleration in growth and development. Thus in the fifth generation teeth have erupted and ears opened on the first day. The eyes opened and the animals were covered with fur by the third day. The testes descended between the fourth and fifth days and the vagina opened in twenty days.

8. In the thymus treated strain of rats the young mature earlier and breed earlier. Thus in the offspring of the third generation of test animals, litters have been cast on the fortieth and forty-fifth days.

9. The effect of thymus treatment is more marked in the offspring than in the parents.

10. Weight curves show an accruing acceleration in each succeeding generation. Animals of the fifth generation weigh more than double normal between the third and the twentieth day.

11. The acceleration and the rate of growth and development in the untreated young born of thymus treated ancestors is apparently not effected through the mother's milk, since in two experiments it occurred

Fig. 4.—Weight curves of thymus test rats and their controls.

when the young were suckled by a control "wetnurse" mother and did not appear in control animals suckled by thymus treated mothers.

12. Thymus extracts made by Hanson's method are not all equally potent, as evidenced by one preparation secured from another source.

13. It has not been determined as yet whether or not thymus extract by mouth is effective. Our own experiments in this connection are subject to criticism.

14. Interruption of thymus administration for one generation nullifies completely or at least to a large extent the effects of previous thymus administration, even though this treatment may have extended through several generations of rats. The lack of thymus effect becomes more striking in succeeding litters.

15. While precocity is lacking in the early litters born of thymus treated parents, it appears in later litters.

16. Rats under thymus treatment appear unusually docile, healthy and contented.

17. Excessive amounts of thymus extract result in toxicity, as evidenced by increasing auriculoventricular dissociation and eventual heart block.

18. From our own investigations, no claim can be made for the specificity of the thymus in this connection. Control studies bearing on this are imperative and in progress.

CONCLUSIONS

1. Thymus extract (Hanson) has accelerated the rate of growth and development, has hastened the onset of adolescence in the offspring of treated rats, and has seemed to increase the fertility of parent rats.

2. The injection of succeeding generations of parent rats has resulted in the amplification of the effects of thymus extract.

CHRONIC ATOPIC ECZEMA (NEURODERMATITIS) IN CHILDHOOD

LEWIS WEBB HILL, M.D.

BOSTON

It is common for infantile eczema to improve with age and to disappear during the second year. This is not always so, however. In a series of 900 cases of eczema in infants and young children, 210 occurred between the ages of 2 and 12 years. In 127 of these the eczema had existed since early infancy; in eighty-three it began after the second year. It is the first group that I propose to discuss: chronic eczema in childhood, which had its inception in early infancy.

This eczema is characterized by papulation and thickening, but with little vesiculation. The classic case shows involvement of the antecubital and postpopliteal spaces, the wrists and the neck. The skin in these areas is dull red and thick, with a few small papules which are excoriated from scratching. It is often very thick and leathery, without much papulation, but with many furrows, and a great exaggeration of the normal lines of the skin; that is, lichenification. Itching is intense, and much of the pathologic condition of the skin is caused by long continued rubbing and scratching. Sometimes the eruption may be scattered all over the body in small plaques and papules.

Dermatologists have given many names to what I shall call "chronic atopic eczema," the most common of

which are "flexural pruritus," "Besnier's prurigo" and "neurodermatitis." Since the disease in childhood, although histologically not strictly an eczema, is the same process, modified by chronicity, that these children had when they were infants, which, according to American nomenclature, was eczema, chronic atopic eczema seems the best term for pediatricians to use. It is atopic because reagins are found in the blood, because it is often associated with the other atopic disorders, hay fever and asthma, and because it usually gives positive intracutaneous or cutaneous tests to proteins. It is to be distinguished from contact dermatitis, which is allergic but not atopic, because reagins are not found in the blood, because it is not associated with hay fever or asthma, and because scratch or intracutaneous tests with proteins are negative but patch tests with non-protein substances are positive.

Some dermatologists would agree with this nomenclature; some would prefer the term "neurodermatitis."

Fig. 1.—Typical eruption.

It is reasonable to suppose that the basic etiology for the disease in these children is much the same as it was when they were infants, and that the difference in clinical appearance is due to chronicity and long continued external trauma.

Protein skin tests were done by the cutaneous method in seventy-four of the more severe cases in the group under discussion, with positive reactions in 77 per cent. In 100 eczematous infants under 1 year of age, skin tests were positive in 63 per cent.

Positive reactions were obtained in thirty cases to egg, in fourteen to cat hair, in nine to wheat, in nine to spinach, and in six to milk. Various other foods and epidermals gave reactions in from one to five cases. The occurrence of egg reactions is less (40 per cent)

From the eczema clinic, Children's Hospital, and the Department of Pediatrics, Harvard Medical School.

Read before the Section on Pediatrics at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

than it is in infants under 1 year (54 per cent), and it is interesting to note that, while the next most common protein to give reactions in infants is lactalbumin, cat hair takes its place in older children. It may be said from my own experience, as well as from that of others, that most children who have had eczema from infancy are atopic. It is likely that other factors are

If positive skin tests are found, there are two possibilities in treatment:

1. Removal of the positive foods from the diet, or other positive allergens from the environment.
2. An attempt at hyposensitization, either specific or non-specific.

Hyposensitization is valuable in hay fever; in asthma it is sometimes worth while; in chronic atopic eczema it may be rarely useful in a limited number of special cases, but by no means as a routine measure.

Specific hyposensitization has been attempted in one of three ways:

1. By feeding gradually increasing amounts of the offending food.
2. By intracutaneous or subcutaneous injections.
3. By the propeptan method of Urbach, in which, before each offending food is eaten, a specific peptone tablet is taken by mouth.

Nonspecific hyposensitization has been attempted by the injection of nonspecific proteins, such as milk, typhoid vaccine, blood or various peptones, or by autochemotherapy.

When I first began working with infantile eczema, the question arose whether any of the methods directed at hyposensitization should be commonly used. After I reviewed the literature, and after talking with various allergists and immunologists, it seemed that these were of very doubtful value in eczema at any rate and not to be compared to hyposensitization in hay fever or even in asthma. In the first place, it is likely not to work,

Fig. 2.—Typical excoriated eruption.

sometimes added, notably staphylococcic and fungous infection.

The treatment of eczema may be summed up in six words: Find the cause and remove it. The first thing in dealing with these patients, therefore, is to determine the causative allergens, if possible, from the history, secondly by skin tests, and, if these are negative, possibly by elimination diets. A positive skin reaction to a food or epidermal by no means always indicates that the eczema is due to that particular allergen.

It has been brought out by Rowe that in food atopy skin tests are sometimes negative in spite of the fact that symptoms are due to some particular food. With this in mind, he devised his ingenious series of elimination diets, which have often proved of value in determining food sensitivity in adults. This procedure is not so well adapted for use in eczema as it is in other food atopies, such as abdominal pain and migraine, for improvement in most cases of chronic eczema is so slow and there are so many other factors involved besides the diet that it is often difficult to judge whether or not a certain diet is doing any good. Also it is not so easy to use these diets for children as it is for adults. Furthermore, with young children it is well not to experiment too much with the diet. In spite of these certain disadvantages the principle is sound, and I have used Rowe's diet 1, slightly modified, as a basic diet, and have then added every week other foods, in an attempt to determine what was or was not harmful. This basic diet consists of rice, lamb, rye crisp wafers, string beans, carrots, celery, peaches, pears and jell-o. Such investigation is worth while in all severe cases with negative skin tests, but I have seen very few clean cut results with it.

Fig. 3.—Close up of figure 2.

and, if it does work, its effect is more often temporary than permanent; in the second place, it may be such a long and tedious procedure that it is not worth while attempting unless very definite beneficial results can be expected; in the third place, it is very difficult to evaluate results in such a chronic process as this type

of eczema, and the skin often becomes worse instead of better during treatment. Most of those in America who have used propeptan therapy are not at all enthusiastic about it, and Urbach himself says that it is of no value in "neurodermatitis" (chronic eczema). Another difficulty is that in chronic eczema there is almost always multiple sensitization; the situation is

Fig. 4.—Lichenification.

different from that in hay fever, in which a single and very definite sensitivity is likely to exist, or in asthma, in which the allergic manifestations are periodic instead of continuous and there are not so often the secondary pathologic changes in the sensitized tissues that there are in chronic eczema.

If there were any method of specific or nonspecific hyposensitization that would cure eczema, it would be universally used. Instead, most allergists are not in favor of it, and those who are use widely varying methods. One must conclude that at the present time for atopic eczema (note that I do not say contact dermatitis, which is a different thing) there is no method of specific or nonspecific hyposensitization that can be depended on to give good results in the majority of cases. For this reason I have rarely attempted it except in a few cases in which it has been obvious that the eczema was almost entirely due to very definite sensitization to one particular common food. I think also that hyposensitization applies more, both in theory and in practice, to those individuals who have really violent symptoms when they come into contact with or eat the substance to which they are sensitive. Such is rarely the case in eczema, for any child who reacts violently to some food never takes enough of it to give him eczema, as it is immediately apparent to the mother that the food in question is a poison to him.

Hypsensitization is not well adapted for use when the original eczema is present, and if tried at all it is better first to prove that it is due to the suspected allergen by removing the latter from the diet and noting results. Then, if after a considerable period of freedom from symptoms eating of the food again causes symptoms, it may be attempted by the oral method.

There is, however, no very good answer to the eczema problem until there is available some permanent and effective method of doing away with atopy in general, perhaps either by changing the chemical balance of the body cells in some way so that the atopic reaction cannot take place or by some method of nonspecific hyposensitization. Nonspecific, because there is multiple sensitivity in so many cases that what is desired is not hyposensitization to one or two proteins but a direct

abolition of the atopic state itself, so that hay fever, asthma and eczema, or any other condition which depends on an underlying atopic constitution will each be treated in the same way. Unfortunately there is today no effective means of bringing about this ideal of nonspecific hyposensitization.

In eczema, avoidance of the offending allergens is at present in almost all cases the most practical treatment, and often in the course of time the child becomes spontaneously desensitized. There are ordinarily not enough food sensitivities to prohibit a satisfactory diet, and there are many effective methods of getting rid of a cat. If apparently offending foods can be withdrawn without harm to the child, all well and good; if he is sensitive to so many that withdrawal is likely to cause loss of weight, it is better to treat the eczema locally and to forget about the diet. Every pediatrician has seen too many babies and young children with eczema dieted too rigidly, often with no benefit to the eczema and much harm to the child.

Proper local treatment is important. It must be remembered that in this sort of eczema the skin disturbance has lasted a long time; the skin has been insulted by many things, and for these reasons more or less permanent changes have been produced in it. With infantile eczema, in which no such chronic changes have taken place, if there is definite sensitivity to one particular food, withdrawal of this is often followed by speedy results. This is not so often true of chronic eczema, and little can be accomplished without skilled

Fig. 5.—Lichenification.

and persistent local treatment. The essential change in the skin is one of cellular infiltration; therefore strong remedies are usually indicated, such as crude coal tar or wood tar preparations, Swartz's ointment (mercurochrome with salicylic acid), and sulphur with salicylic acid. If there are small circumscribed patches, painting with crude coal tar undiluted is very effective, especially for cracks at the lobe of the ear.

Chronic eczema is not cured over night, and local treatment must be persisted in even if results are at first disappointing. In cases in which there is much lichenification, roentgen treatment is usually of value in resolving the infiltration and in relieving the itching. Its results are likely to be only temporary, however, and with repeated exposures there is some danger of causing atrophy of the skin.

It is very difficult and usually misleading in any such chronic condition, which is so subject to relapse, to tabulate therapeutic results in percentages of cured, improved, and so on, and I shall not attempt it. It may be said, however, that results are fairly good. Some patients are cured, many are relieved, but recurrences are common. There are a few cases of the diffuse type, with redness and thickening all over the body, for which little can be done, even by the most skilled dermatologist.

To talk about eczema is easy and always pleasant; to cure the patient is quite another matter, and in spite of allergens, reagents, skin tests, elimination diets, and so on, the actual practical treatment is not entirely satisfactory, whether by dermatologist, allergist or pediatrician, or by all combined. It can never be so until there is available some good and consistent method of attacking the atopic state itself.

I am not in the least pessimistic about eczema—merely trying to see the situation honestly as it is and not as I would like to see it. The understanding of this disease is constantly increasing, but there are many things still to be explained, and the kernel of it has by no means as yet been reached. In no disease is it easier to make erroneous observations or to draw false conclusions from correct observations.

There is no subject in pediatrics in which a sound conservatism and an unbiased critical attitude are more necessary.

319 Longwood Avenue.

ABSTRACT OF DISCUSSION

DR. MARION B. SULZBERGER, New York: Dr. Hill's ideal of finding the cause of infantile eczema and then removing it is, with present methods, often impossible to realize; for substances that are the actual causes of the eczema frequently give negative skin tests and, on the other hand, not all substances that give positive skin tests prove to be the etiologic agents. Egg white, for example, gives many positive wheal reactions, even in infants whose eczemas continue without ingestion of egg constituents in any form or by any conceivable route. Therefore the various test methods, including elimination diets, are still so likely to give inconclusive, not to say confusing, results that they must often be dispensed with. While skin tests are essential in the scientific studies of eczema, and sometimes indispensable even in the management of the individual case, in many routine cases a logical plan of therapy can first be tried. This may give satisfactory results and obviate the necessity for skin testing. Local and roentgen therapy are sometimes sufficient to achieve a cure, but the manner in which the local remedies are applied may determine success or failure of the treatment. Simple change of environment, or hospitalization, sometimes causes an abrupt remission. In the immunologic approach, the differential diagnosis between contact eczema, atopic dermatosis and seborrheic dermatitis should be made whenever possible. This is often difficult. However, it is most desirable, because the elimination of environmental and dietary allergens is presumably of no benefit in most cases of true seborrheic dermatitis. In both atopic and contact dermatoses, the practical immunologic approach may best be expressed by the word "change." Change the environment and the diet, as far as this is compatible with the maintenance of health and proper nutrition. Particular attention should be paid to the bedding material and to the

sources of dust in the room. All who have seen rapid cures under simple elimination of one or more of the commoner causative agents will agree that, although unfortunately rare, these cases justify the recommendation to study the infant's environment and to change it as much as possible, without jeopardizing the general state of nutrition and health. Fungi, as mentioned by Dr. Hill, may prove to play an important rôle in some infantile eczemas. Particularly fungi of the *Monilia* group seem to me to be most suspect, for these organisms are ubiquitous, are strong sensitizers, and have been proved capable of causing eczematous eruptions in adults. What I have said about fungi may apply, but to a less degree, to other micro-organisms. For another reason it is important to differentiate atopic from contact dermatitis whenever possible. It is probable that, in pure contact dermatitis in infants, foods will be of little or no significance, and elimination diets of little or no promise. Differentiation between contact and atopic dermatitis is generally possible in adults; in infants it is usually found to be difficult.

DR. J. VICTOR GREENBAUM, Cincinnati: I noticed that Dr. Hill had 127 cases of this condition. Judging from our experience in Cincinnati, this is indeed an unusually large number of cases. That reminds me of a story that probably is familiar to many. A young doctor years ago, on being asked the specialty in which he intended to enter, answered "infantile eczema." On being asked the reason for this unusual decision, he answered: "First, because there are so many of these cases; second, these cases never get well; third, these cases never die, and, fourth, these cases never bother you at night." I hope this young man did not come to Cincinnati, because, first, there are rather few cases in Cincinnati; second, the patients frequently get well; third, they sometimes die, particularly if they are sent to the hospital, as brought out by Dr. Schwartz in his report, and fourth, I know from experience that they do bother you at night. In Dr. Hill's summary, he stated he would give results of his group, but I noticed he said he could not draw any conclusion from the results and therefore would not present them. In ten years' time at the Cincinnati General Hospital, we have had sixty-one cases listed under the diagnosis of eczema in the pediatric service. Seventeen of these cases had to be discarded as improperly diagnosed, leaving forty-four cases of undoubted eczema. Of these cases, twenty-six entered the hospital for treatment of eczema. Incidentally complications, chiefly of the respiratory tract, developed in twenty-one of these twenty-six. Skin tests were made in six cases. The dietary changes based on the skin tests were made, resulting in four patients improved, one unimproved and one recovered. Of the remainder, eighteen recovered, twenty-four improved, one died and one case was intractable. All sorts of treatment were used, including tar and mercury. It can be seen from these results that 36 per cent of these babies recovered and 59 per cent improved, giving a total of 95 per cent showing favorable outcome. I have gone over the cases during the past five to six years in the Jewish Hospital, in the Cincinnati General Hospital outpatient clinic, the Children's Hospital, and the Children's Hospital outpatient department, and they total to the surprisingly low number of approximately seventy.

DR. GEORGE PINES, Los Angeles: Dr. Hill's paper gives one the impression that the etiology in chronic atopic eczema is most difficult to determine, therefore not warranting the time and effort that are put forth in testing these cases. One is justified in this opinion if he takes the attitude that foods alone cause this disease in children. This is the impression of most pediatricians. In the experience with the clinic of the Children's Hospital in Los Angeles, over a period of eleven years I found that there were as many children that were sensitive to things other than foods, resulting in eczemas. Shortly after a child is born he is in contact with as many things as an adult and one should study him as an adult instead of as an infant. Reactions in children are rarely limited to food alone. In a review of 1,500-odd allergic infants at this clinic it was found that foods, and foods alone, were present in only one out of each hundred cases studied; in other words, foods as an etiologic factor alone are present in 1 per cent of the total cases studied. Incidentally, it was found that the other 99 per cent of positive cases were multiple sensitive,

the incidence of foods being present in about 70 per cent, about 19 per cent being environmental factors, and the remainder being those of pollen and the like. I agree with Dr. Greenebaum that deaths occur from eczema, particularly in those children brought to the hospital. They seem to be in good physical condition but suddenly have severe diarrheas, become dehydrated, then after a short period with a high fever, die.

DR CHARLES HENDEE SMITH, New York: There is no problem that is so trying to the pediatrician as the case of chronic eczema. A more or less standard procedure has been adopted in the department where I see these cases. In the first place, we find rather more of them due to diet than was suggested by the last speaker. We therefore put each infant with eczema on a diet of evaporated milk, appropriately diluted, which has been boiled four hours. This follows the suggestion of a clinician with long experience, Dr. Charles Gilmore Kerley. Ratner, in our department, has found by animal experimentation that evaporated milk boiled four hours is the least anaphylactic agent of the various types of milk. To this we add boiled rice. It is possible to keep a child on boiled evaporated milk formulas and rice for a long time, with the addition of some fresh fruit or vegetable juice. Other foods are added slowly. Appropriate local treatment must not be forgotten. The old principle of soothing the acute cases and stimulating the chronic ones holds as much today as ever. I notice that most of the speakers today have dismissed the local treatment as if it were all a matter of ointments. In the acute, oozing stages we use a simple zinc and starch paste, 25 per cent each in petrolatum. The starch lets the secretion through from the inside. It must be remembered that this is not Lassar's paste, which contains 2 per cent of salicylic acid, an irritating substance. The zinc and starch paste is used on a mask or dressing until the oozing has ceased. After this and before stimulation is needed, we have devised a drying paste of considerable value, namely, a zinc paste with K-Y jelly base. When this jelly dries it leaves an elastic coating which protects the skin from the air. We use 2 drachms (8 Gm.) of zinc oxide, 2 drachms of calamine, 2 drachms of magnesia magma and one tube of K-Y jelly. If mixed thoroughly, it can be applied in a thin smooth layer which needs no dressing. It gives a great deal of relief from the itching, which is due to the microscopic cracking of the skin, allowing access of air. It is excellent for poison ivy as well for the same reason. Coal tar is not the answer for stimulating all chronic cases. It burns some skins like liquid fire. This rarely occurs with good old oil of cade.

DR LEWIS H. HILL, Boston: If I were restricted to one routine food for use in infantile eczema, I should probably choose evaporated milk. I should not care to boil it, because it has already been heated to 240 Fahrenheit. There is this, however, about evaporated milk and the other superheated milks. Lactalbumin is very considerably denatured in the process of heating, if the milk is heated very hot. Casein is probably not changed by heating, no matter how long it is heated. In most cases of milk sensitivity in infants and children, the sensitivity is to casein as well as to lactalbumin, so, therefore, if there is a double sensitivity, evaporated milk or boiled milk or superheated milk is likely to do no good. If the sensitivity is to lactalbumin alone as determined by the skin test, evaporated milk or boiled milk or superheated milk may be very valuable. I have had prepared for me a preparation of milk that has been heated to 130 C for an hour, much hotter than evaporated milk, is heated. I am able, with that preparation, to get very large positive skin tests in most babies who show casein sensitivity.

Sunlight and Vitamin D.—Vitamin D differs from most of the other known vitamins in the relative paucity of its distribution in common foods, egg yolk and butter being the only sources which contain it in fair abundance, unless such substances as cod liver oil are included as common foods. This fact seems to indicate that man is expected to derive his necessary supply of this vitamin from exposure of his body to sunlight.—Colwell, S. J. *Vitamins in Clinical Medicine, Practitioner* 132:15 (Jan) 1934

USE OF RECONSTRUCTIVE SURGERY IN CERTAIN TYPES OF DEFORMITIES OF THE FACE

GORDON B. NEW, M.D.

AND

FREDERICK A. FIGI, M.D.

ROCHESTER, MINN.

A large number of deformities, for correction of which reconstructive surgery is required, are seen primarily by laryngologists. Consequently, we are considering some applications of the principles of this type of surgery for certain types of deformities of the face that are of especial interest to laryngologists.

There are certain general principles in reconstructive surgery that are the same whether applied to this field or to others. Some of these principles are applied in the making of a tubed flap, a delayed flap, a full-thickness skin graft or a Thiersch graft, or in the grafting of bone or cartilage. However, in operations about the face certain problems require additional consideration, owing to local anatomic, functional and cosmetic requirements. No field of surgery requires more careful preoperative study, exacting surgical technique, care in handling tissues, and close postoperative observation.

Of the many deformities that occur about the face, we have selected for consideration four types that should be of interest to the laryngologist. These have no special relation to one another, aside from the fact that they present current problems in reconstructive surgery: (1) some nasal deformities that may be corrected by adjustment of the cartilages; (2) syphilitic nasal deformities; (3) deformities secondary to the removal of intranasal and antral tumors, and (4) deformities of the forehead, the result of osteomyelitis or the removal of tumors involving the frontal sinuses.

SOME NASAL DEFORMITIES THAT MAY BE CORRECTED BY ADJUSTMENT OF THE CARTILAGES

A great deal has been written about the use of cartilage or bone to correct various deformities of the nose, but not sufficient attention has been given to reshaping and adjustment of the nasal cartilages in the correction of certain types of these deformities. This is particularly true of the deformities that follow operation for harelip of adults. Metzenbaum¹ has presented an excellent piece of work, showing the anatomic displacement of the nasal framework that results from dislocation of the lower end of the septum.

In the deformity resulting from operation for harelip of adults, the median line of the nose frequently is displaced laterally, both the basal bones and the cartilage. The greater alar cartilage, on the flattened side, is displaced backward, the ala is flattened and flared outward, and its lower margin has a marked convexity similar to the turned down brim of a felt hat. The vestibule of the nose lies with its long axis laterally, or obliquely, instead of anteroposteriorly (fig. 1).

Correction of this type of deformity requires chiseling free of the nasal bones and setting them over into correct alignment, rotating and bringing forward the

¹ Metzenbaum, Myron. Asymmetry of the Nares, *Arch. Otolaryngol.* 16: 690-697 (Nov.) 1932.

greater alar cartilage, and rolling in the posterior part of the ala. It is advisable to cross-hatch the cartilage posteriorly to eliminate the spring and, following this, to hold the nose in position by means of lead plates and tension sutures. The convex lower margin of the ala must be made like its fellow. It is sometimes necessary to skin-graft the sulcus after freeing up underneath

Fig. 1.—*A*, deformity after operation for harelip. The following may be noted: displacement of the nasal bones and tip of the nose, flattening of the left ala, the short upper lip, and irregularity of the vermilion margin. *B*, postoperative appearance. Correction of the deformity of the nose and upper lip has been effected.

the lip in order to allow insertion of a plate to hold the nose and upper lip forward. A much more marked deformity is present after operation for double harelip of adults; features of this deformity are the wide nose with rounding of the tip, the short columella and frequently the bilateral flaring of the alar cartilages. Elevation of the tip of the nose, lengthening of the columella at the expense of the upper lip, and narrowing of the entire lower cartilaginous part of the nose are necessary. Sometimes excision of an elliptic piece of cartilage from the median line is required in order to narrow it sufficiently. The cartilages forming the flattened, wide tip may be unfolded, brought forward and sutured in place with chromic catgut to form a more normal looking tip. The ala on either side should be rolled in posteriorly after cross-hatching (fig. 2) has been done.

Dermoids of the nose require careful excision and adjustment of the cartilages, because of the situation of the sinus between the nasal bones. Widening of the nose in some cases may require chiseling free of the nasal bones and adjustment of the superior and lateral cartilages to build up the bridge after excision of the cyst.

SYPHILITIC NASAL DEFORMITIES

Syphilis that causes nasal deformities may be of congenital or acquired type. The outstanding feature of this type of deformity is loss of the bony structure and cartilaginous and mucous membrane lining the nose, producing a change that may vary from a slight saddleback deformity to a crumpled mass of skin and tissue, with loss of the columella.

In the congenital type there may be flattening of the face, producing a saucer-shaped deformity, with a very small nubbin of cartilaginous nose, with flattening of the bridge. Replacement of the lining of the nose, either by means of a full-thickness skin graft or a

pedicled flap, is necessary in most cases in order to reconstruct the nose. Gillies suggested the use of Thiersch grafts on dental compound attached to a splint fixed to the teeth to replace the lining, after the skin of the nose had been freed. We have used a similar procedure, employing a full-thickness skin graft, with satisfactory results (fig. 3). This produces two thicknesses of skin between which costal cartilage may be inserted to correct the saddleback deformity. In some cases a post may be necessary in addition, in order to raise the tip of the nose. A removable appliance consisting of a vulcanite tip on a stiff wire, attached to the upper teeth, may be necessary to hold the tip forward in position in certain cases (fig. 4). If a pedicled flap is used to replace the lining, this is usually best taken from the upper part of the arm, and, after delay, it is brought up into position, carried in back of the nose, either underneath the upper lip or through the base of the columella, and held with mattress sutures, the arm being fixed to the head by means of a cast or other suitable device. In congenital deformities reconstruction of the columella is most satisfactorily done by elevating a flap from the center of the upper lip, the base of the flap being where the base of the columella should be, and the distal end of the flap extending down to the vermilion border. The undersurface of the flap is lined with a full-thickness skin graft at the time of the original elevation and then sutured back in place on the upper lip. In ten days the flap is elevated again; the distal end is brought up to a point just behind the tip of the nose, and the wound in the upper lip is closed. The skin graft forms the antero-inferior surface of the columella. Certain congenital nasal deformities require only a cartilage implant to correct the deformity, while others are so marked, with loss of tissue, that total rhinoplasty offers the best solution, a line forehead flap being used. The use of horseshoe-shaped pieces of

Fig. 2.—Nasal deformity, the result of a dermoid cyst: *A*, displacement of the nasal cartilages may be noted. *B*, following removal of the dermoid cyst and adjustment of the nasal cartilages.

cartilage to stiffen the columella and alae, as suggested by Webster,² is a distinct advance in total rhinoplasty.

DEFORMITIES SECONDARY TO REMOVAL OF NASAL AND ANTRAL TUMORS

A very small percentage of patients require reconstructive surgery to replace a portion of the nose or

2. Webster, J. P.: Personal communication to the authors.

cheek following lateral rhinotomy or destruction of a malignant antral tumor by diathermy and radium. They usually present an opening laterally in the nose and cheek, or a deformity, with loss of tissue and perforation through the anterior wall of the antrum. In a small percentage of cases the eye is lost. A lined pedicled flap from the thorax or back is the best method of replacing this tissue. If the patient is a woman the forehead may be used. The area from which the tissue to replace the deformity is obtained should be carefully selected, so that the character of the skin simulates the skin of the face. The skin in the region of the clavicle is usually suitable for this purpose. The tubed flap is elevated, extending from the clavicle down over the thorax, and then the lower end is carried to the mastoid region. The upper end of the tubed flap in the region of the clavicle, which is lined with a full-thickness skin graft, is carried to the face to replace the lost tissue. The lining should be supplied in all these cases. This may be turned in from surrounding tissues of the cheek or supplied by means of a full-thickness skin graft, lining that portion of the flap that will be used in the cheek.

Fig. 3.—Syphilitic nasal deformity, with loss of the lining of the nose. A full thickness skin graft on a Stent's compound splint attached to the upper teeth and carried up into the nose through an incision underneath the upper lip was used to replace the lining of the nose, after the nose had been freed up and the scar tissue excised from the inside. A cartilage implant was inserted later, between the skin and the full-thickness skin graft lining of the nose. A, before reconstructive operation; B, postoperative appearance.

In most deformities following removal of malignant tumors of the antrum, with loss of the eye, there is so much deformity that an attempt to reconstruct the socket so that an artificial eye can be worn is usually not satisfactory. Covering of the orbit and cheek at the same time usually is the best method. If there is sufficient scarring inside the mouth, due to loss of tissue of the cheek, to cause ankylosis of the lower jaw, replacement of this tissue by means of a tubed flap from the thorax is advisable. The flap is brought up so that its distal end is carried into the mouth and sutured in place to cover the raw surface remaining after excision of the scar tissue. The mouth is kept open temporarily by means of a rubber gag. Large openings into the antrum, through the palate and upper jaw, are much better closed by means of a vulcanite plate; not only does this close the opening but teeth may also be attached to it. Kazanjian³ states that, as

a rule, if a flap is used to close large openings in the palate, it is impossible to hold a denture in position. A dental plate is much more satisfactory, for it closes the opening and also supplies the lost teeth.

DEFORMITIES OF THE FOREHEAD, THE RESULT OF OSTEOMYELITIS OR REMOVAL OF TUMORS INVOLVING THE FRONTAL SINUSES

Replacement of the soft tissues of the forehead may require full-thickness skin grafts, pedicled flaps or

Fig. 4.—Syphilitic nasal deformity: A, loss of the framework of the lower two thirds of the nose, and flattening of the face may be noted. The lining of the nose was replaced by means of a pedicled flap from the upper arm. The flap was also used to reconstruct the floor of the nose and to bring forward the upper lip. B, postoperative appearance.

tubed flaps; the latter are used when tissue is brought from a distance. Full-thickness skin grafts are used in clean wounds in which the bone is not involved.

Fig. 5.—A, postoperative deformity of the nose, antrum and ethmoid region, two years and seven months following removal by surgical diathermy and radium, of an epithelioma of low grade. The tumor had bulged this region so that it was necessary to remove the bone at this point. B, postoperative appearance. A double-epithelized tubed flap was brought up from the back to replace the lost tissue.

The technic of cutting and suturing them in place, with careful hemostasis and application of even pressure, must be followed to insure a large percentage of takes.

If an area of exposed bone, the result of osteomyelitis following irradiation or removal of a tumor, is present, it is advisable to remove the entire sequestrum with

3. Kazanjian, V. H.: Personal communication to the authors.

chisel and bone forceps. To cover this area a delayed pedicled flap composed of skin from the nearby forehead or scalp is most satisfactory; the area from which the flap is taken is covered with a full-thickness skin graft at the time the flap is placed in position (fig. 5). A temporary covering of an area of the forehead from which the periosteum has been removed in a clean wound, due to removal of a tumor, by a bipedicled flap with a pedicle in either temporal region saves a great deal of time. A bipedicled flap is brought down from the scalp to the forehead as a visor and after being left in position ten days the flap is dissected free again and replaced on the scalp in its original position, leaving sufficient tissue over the forehead from the under surface of the flap to allow covering it with a full-thickness skin graft. The larger areas of the forehead in which bone has been denuded, and those in which the frontal sinuses have been opened, require tubed flaps which may be brought up satisfactorily from the back or thorax in stages.

ABSTRACT OF DISCUSSION

DR. SAMUEL IGLAUER, Cincinnati: As pointed out by the authors, the general principles of plastic surgery apply to reconstructive surgery of the face. However, greater care must be taken in approximating the skin edges, and the stitches should be removed as early as possible and replaced by collodion cover straps of gauze to hold the edges in apposition. When flaps are used it is important to have the skin of the flap match that of the face in color and texture. Forehead flaps match better than skin from other parts of the body. The secondary contraction resulting from operative incisions is to be anticipated. Alar deformities remaining after a good harelip operation frequently require correction. The flattened ala should be approximated to the septum and, as pointed out by Blair, a wide undermining of the cheek about the ala tends to prevent the recurrence of the deformity. In the correction of the saddle nose deformity in which a lining and a covering flap are used, it is important to have the covers sufficiently loose to permit of the easy introduction of a cartilaginous implant between the flaps. In common with Drs. New and Figi I consider costal cartilage the best substance for implantation. I should like to inquire whether the authors consider anti-syphilitic treatment of any special value in congenital syphilis before undertaking a plastic operation on the nose. For certain depressed deformities of the cheek, the implantation of fat is desirable. In two cases of facial hemiatrophy, by making an incision in front of the ear and the hair line and then depositing the fat under the skin into the depression, a very good cosmetic result was obtained. The fat implant should be somewhat oversized, as it is subject to shrinkage. The deformities of the face after surgery for malignant disease are very distressing but still are of minor importance in comparison with the original malady. Closure or covering of such defects for cosmetic reasons should not be undertaken until it is certain that there is no recurrence of the malignant condition.

DR. FIELDING O. LEWIS, Philadelphia: The authors are to be congratulated on their splendid results. It has been my experience that plastic surgery about the nose and face is very difficult and that satisfactory cosmetic results are hard to obtain, no matter how simple the defect may be. This method of correcting nasal deformities resulting from imperfect harelip operations and from accidental happenings merits special emphasis. I know of no nasal deformity comparable to them in which such a uniformity of bad results can be obtained. Nasal deformities due to syphilis often tax the ingenuity of the surgeon. When the bony and cartilaginous framework have been largely destroyed, the remaining skin is usually so crumpled and distorted by scar tissue that complete rhinoplasty offers the best solution. In syphilitic subjects, one should always bear in mind to make ample allowance for the shrinkage in skin flaps, for it has always seemed to me that there is much

more contraction of the skin in syphilitic patients than in others. Deformities resulting from operations for malignant disease involving the face, sinuses or a portion of the nose require meticulous care. These patients have usually been treated, in addition to surgery, with maximum doses of x-rays or radium or both. As a result there is an extensive fibrosis of the skin, which, owing to the lack of blood supply, greatly hinders and oftentimes completely defeats the taking of the skin flaps. If one is not able to go beyond the area of fibrosis, prosthetic repair is preferable. In cases in which there has been enucleation of the eye, together with antral and other sinus operations, my experience would lead me to advise caution against any hasty attempt at plastic repair, for usually, if one delays, much time and hard labor are saved by the appearance of recurrences, which almost invariably take place.

DR. GEORGE B. JOBSON, Franklin, Pa.: About thirty years ago I began the practice of plastic surgery of the face and mouth in conjunction with our specialty. At that time, only a very few were giving this branch attention, and the methods then were somewhat crude as compared with those of today. During the World War great advances were made, and the improvements instituted then are being used in civil life today by many operators. I wish to present a method for the correction of a cauliflower ear, which has proved successful in several cases. The condition is the result of hematoma auris, which becomes organized into cartilage and scar tissue. Correction is accomplished by making an incision just internal and parallel to the rim of the ear. The skin is carefully dissected from the inner and outer ear surfaces, to the side of the head, if necessary. The auricular skeleton is then sculptured into shape by scissors and scalpel. If absences of continuity of the rim exist, these may be corrected by stitching in pieces of the removed ear cartilages with absorbable catgut. The skin flaps should have several small incisions made in them for drainage; then they are drawn over the modeled ear skeleton and their edges united with interrupted sutures. Half a dozen mattress sutures may be passed through both layers of skin and the cartilage in the depressions to facilitate union. Pieces of small rubber tubing or rubber tissue should be placed beneath the loops of the stitches to prevent cutting. Even pressure must be maintained by filling all irregularities with pieces of cotton wet with saline solution and allowing them to remain until healing takes place. A gauze pad and bandage are applied.

DR. CLAIRE L. STRAITH, Detroit: The authors have brought out beautifully many of the essential things required in producing satisfactory results cosmetically, at least, in facial deformities. In a nose, usually in a total loss, at least, it is the lining, covering and lastly the support, which is introduced later, usually of cartilage, that have to be restored. I wish to confine my remarks to the covering, or the integument used. As has been mentioned, the Indian method, or bringing down a forehead flap, works beautifully in women, but men unavoidably have to go through life with a forehead scar, no matter how nice a scar is produced, by bringing the flap back and then grafting this forehead. For two years I have been using the skin just beneath the ear, which, in men, is practically free from hair, matches the face beautifully, and is easily brought into place with one transfer. So far as I know, this method hasn't been reported before. I first used it in a boy, who, as a baby, was leaning with his nose against a window pane when some one broke the glass. The glass slid down, cutting off the integument over the bridge of the nose and the tip and columella. At the first operation I raised a flap from the skin beneath the ear to the sternoclavicular notch, bringing the edges together to form a tube pedicle. Three weeks later the scar tissue over the bridge of the nose and surrounding the wound was turned in, wrong side out, to produce a lining. The pedicle was detached at its upper end, following the pattern of the new nose and the skin stitched onto the nose in the new position. I put his head in a cast with a connecting band to the chest cast to maintain this position for the next two weeks. The skin was then detached and shaped around the tip of the nose. After this operation, a nice result can be obtained. The procedure provides a graft with one transfer, which matches perfectly the skin of the face, is

practically free from hair, and does not leave a disfiguring scar. It is much better than the Italian method of bringing up the arm skin, because the Italian method produces a skin covering that does not match the face.

DR MYRON METZENBAUM, Cleveland. Three things necessitate reconstruction of the cartilaginous or lower half of the nose. The upper bony half of the nose has an outside bony framework, which is self supporting, and a bony septum. The entire lower half of the nose has a cartilaginous framework and an entire cartilaginous septum, which is the only supporting structure to the lower half of the nose. When the cartilaginous septum is weakened or dislocated, the lower half of the nose may droop or drop to such a degree as to necessitate some type of reconstructive surgery to reestablish normal nasal function. The most frequent injuries to the lower half of the nose are those which occur from infancy to about the age of 10 years. One of the serious results of injuries to the cartilaginous septum is due to hematoma, which is usually bilateral because the same force affects the covering of the septum on the two sides. There is frequently a fracture of the cartilage, allowing the blood to seep through from one side to the other. A hematoma should be opened by a wide incision on both sides, the clots removed and the perichondrium packed close to the cartilage on both sides. If suppuration takes place, the cartilage, especially in young children, will be weaker or large areas will be rapidly destroyed. Secondly, nasal reconstruction of the tip of the nose later in life may be necessitated by injuries to the tip of the nose causing fractures and dislocations resulting in nasal obstruction. Displacements of the lower end of the cartilaginous nasal septum may be recognized by the asymmetry of the nares. Replacement of the dislocated septal cartilage should be done for the same reason that the supporting structures in any other part of the body, when displaced, are replaced to reestablish normal function. Thirdly, the results of the submucous resection operation may necessitate reconstruction of the supporting tip of the nose. The cartilage has no circulation of its own and receives its nourishment from the perichondrium on both sides. When the submucous resection is performed, the perichondrium, if stripped from the entire cartilaginous septum, may cause the remaining cartilage to become like a piece of blotting paper that has been dampened and ever after lacks the ability to support the tip of the nose. Normal nasal function depends on the perpendicularity of the lower end of the cartilaginous septum.

DR GORDON B. NEW, Rochester, Minn. Regarding Dr Metzenbaum's work, I would say that it was mentioned in the paper and that Dr Figs and I believe it to be an advance in its particular field. Dr Straith spoke of the color and texture of the flap in rhinoplasty and advocated using the neck for this purpose. I believe that, for women whose foreheads may be covered by their hair and for men with thin skins on whom full-thickness skin grafts seem to show but little, the forehead should be used for total rhinoplasty. The use of artificial appliances for temporarily replacing the loss of a nose has a definite place, although total rhinoplasty should be done, as most patients are not satisfied to wear any type of artificial nose except as a temporary measure. Dr Lewis's discussion regarding the time to do these plastic operations is important. I wait at least a year following removal of a malignant growth before attempting reconstructive surgery. For deformities about the face, when a considerable amount of irradiation has been given and a large area is to be replaced, the tissue is best brought from a distance, a tube flap being used. As a rule, the blood supply about the area is destroyed and it is difficult to get a flap about the area that is satisfactory. Regarding operation on patients with congenital syphilis, I would say that in the past most of the Wassermann tests have been negative. As a result of the recent development of more sensitive tests, serologic examinations are more likely to be positive. Such patients should have preoperative antisyphilitic treatment. Regarding Dr Iglauer's question as to an external method of holding wounds together following operation, there is an English mixture called "mastisol" which we paint on the skin and apply tape to this. I find it much better than adhesive tape for this purpose.

NUTRITIONAL XEROPHTHALMIA

J. A. THORSON, M.D.

DUBUQUE, IOWA

Early Egyptian literature and the teachings of Hippocrates are quoted as prescribing a liver diet for hemeralopia, one of the symptoms of avitaminosis. By recent experiment,¹ this therapy has been proved scientifically correct. In 1857 Livingstone,² describing a disorder of the eyes in members of his African party, wrote that the eyes became affected, as in the case of experimental animals fed on pure gluten or starch, yet it was not until fifty-five years later that Hopkins³ first gave definite proof of the existence of fat soluble vitamin A. In the following year, 1913, Osborne and Mendel⁴ experimentally produced characteristic xerophthalmia and proved that it could be cured, in rats, by the addition of butter fat or cod liver oil to the deficient diet. From this time until 1922, when McCollum and his associates⁵ differentiated vitamins A and D, many of the abnormalities reported following clinical observation and experimental studies, thought to be due solely to vitamin A deficiency, were really due to a deficiency of vitamins A or D or both.

As with similar food factors, the absence of vitamin A is most effective in infants and children or during the period of growth. Reports of large epidemics among an entire populace, such as those in Russia (1887) during lenten fasts, in Japan (1896) and in Denmark (1917), are, in effect, reports of children's diseases. It was not the fasting Russian mothers but their nurslings in whom keratomalacia developed. Adults, however, are not immune and will succumb if the food deficiency is severe enough. The poorly fed soldiers of northern China have been an actual laboratory for the study of avitaminotic ophthalmia.

The relatively high degree of tolerance to dietary deficiency disease in adults explains the rare incidence in mature life. Since the discovery of vitamin A, four cases of xerophthalmia in adults have been reported in the United States. Crohn and Rosenberg⁶ in 1924 observed two cases of inflammation of the conjunctiva and cornea in patients with colitis, who were on a restricted diet. The eye condition did not respond to local treatment but cleared up readily when the patients were given a sufficient diet. Two years later Wohl⁷ reported a case of beriberi and xerophthalmia in a school teacher, aged 32, who had had severe diabetes for six years. The dull, dry and opaque corneas quickly responded to a proper diet and insulin.

Davis,⁸ in 1932, reported the case of a widow, aged 65, who had lived in a village hotel for eighteen months prior to his observation. She had spent two months in bed. The corneas were opaque stippled and lusterless.

Vision was limited to counting fingers at a distance of 2 feet. At the end of three weeks, during which her diet was rich in green vegetables, butter fat and viosterol, she recovered completely with a corrected vision of 20/30.

The susceptibility of childhood, the scourge of chronic illness and the ravages of famine, as has been noted, are the usual precursors of xerophthalmia. These con-

Fig. 1.—The left eye at the time of the first examination. The marked inflammatory changes of the conjunctiva are shown.

ditions were strikingly absent in the case to be reported. The patient had no other ailments and lived in the "land of plenty." His very occupation was the raising of food which is the chief source of vitamin A.

REPORT OF CASE

A. B., a farmer, white, aged 53, unmarried, was brought in by a neighbor on account of rapidly failing vision. Since 1928 he had been troubled every winter with swelling of the eyelids, pain in the eyeballs, tearing, photophobia and yellowish discharge. This condition would clear in the spring.

Since the death of his mother in 1924, he had lived alone. His diet consisted of potatoes, bread, oatmeal, sugar, thoroughly cooked meats including beef, pork and pork sausage; oranges, radishes and cabbage in season; he would eat eggs in the spring until June, but did not use them thereafter because of doubtful freshness; he used no milk, cream or butter, and drank black coffee.

The patient entered a hospital in February 1929 with diminished vision, tearing, photophobia and a "rough feeling" in the eyes. The diagnosis was kerato-iritis with the possibility of malacia. He was given the regular hospital diet. Local treatment included drops of 1 per cent atropine solution and hot applications for twenty minutes followed by instillation of 1:5,000 mercurial ointment every three hours during the day. At this time smears and cultures from the conjunctival sacs showed staphylococci in predominance. A tuberculin test and three Wassermann reactions, one after a provocative dose of neoarsphenamine, were negative. The urinalysis was negative; the white blood cell count was 6,300. The patient made a complete recovery in one month. He was told to add oranges and fresh vegetables to his diet.

During the winter of 1931-1932 he consulted an oculist because of a return of the symptoms. At this time the corrected vision of the right eye was 20/200, and that of the left eye 20/25. Most of the depression of vision in the right eye was due to scarring. No definite diagnosis was made. He was given zinc collyria and mercurial ointment for local treatment and asked to return in one week. He did not return.

He came for relief of the present attack Feb. 6, 1934. About the time of the preceding Thanksgiving the eye began to pain and the lids became swollen; one month later vision began to fail and became gradually worse. Ocular pain increased until one week before admission, when it ceased entirely. He was now unable to see to do his usual work. He was losing strength and felt unsteady on his feet.

On physical examination he was mentally slow and unsteady on his feet, but there were no abnormal neurologic signs. He was fairly well nourished; the hair and skin were dry. A papular eruption was present on the forehead, neck and back. The few remaining teeth and surrounding gums were markedly infected. He had several whitish plaques on the inner surface of the lower lip. The mouth, nose and pharynx were dry and showed a slight grayish pallor. No abnormality of heart, lungs, abdomen or extremities was noted.

The most striking feature of the right eye was the peculiar dryness of the cornea; it was opaque and lusterless; the lid margins were moderately swollen and the lashes were covered with a dried greenish yellow exudate. There was congestion and thickening of the lid and bulbar conjunctivae, more marked around the limbus and over the lower lid. Pigmentation was not found anywhere in the conjunctival sac. When fluid was dropped on the eyeball it was shed as though the surface had been oiled. The normal sensitivity of the cornea was absent, the surface was irregular and there were eight superficial vessels extending from all around the limbus to the center. A lace of smaller superficial capillaries encircled the limbus like a fringe 1 to 1.5 mm. wide. The anterior chamber was of average depth; only the color of the iris was distinguishable. The pupil was 2.5 mm. wide and was half filled with a central clump of pigment. It was not dilated by a 1 per cent solution of atropine. A fundus reflex was not obtained. The vision was limited to counting fingers at 10 inches.

The most striking feature of the left eye was the thick, beefy red appearance of the bulbar conjunctiva. The lid margins were swollen and covered with a yellow exudate; the lid conjunctiva was red and thickened. The conjunctival swelling

Fig. 2.—The left eye at the time of the second examination. The improvement after treatment is shown.

was so pronounced at the limbus that it was level with the corneal surface. The cornea was insensitive. At the nasal side was an ulcerated area 3 mm. by 4 mm., through which Descemet's membrane was bulging; the remaining surface was irregular and lusterless. A fringe of capillaries 1.5 mm. wide encircled the limbus. The lower third of the anterior chamber was filled with pus. The hazy outline of the pupil measured 2.5 mm. in diameter and only the color of the iris could be defined. No fundus reflex was obtainable. The vision was limited to hand movements at 1 foot.

At the time of admission the temperature was 98.4 F.; the white blood cells numbered 7,500; the differential count showed neutrophils 68 per cent, small lymphocytes 22 per cent, large lymphocytes 6 per cent, eosinophils 1 per cent, basophils 2 per cent and transitionals 1 per cent. The red blood cell count was 4,410,000; the hemoglobin was 85 per cent. There was an occasional hyaline cast in the urine. Staphylococci were predominant in the conjunctival smears. Examination of scrapings just external to the limbus revealed keratinization of the cells. The general treatment consisted of the regular hospital diet with the addition of 90 Gm. of butter, 24 ounces of 12 per cent milk, cereal with 4 ounces of 20 per cent cream and 2 ounces of a malt syrup containing 13,500 U. S. P. units of vitamin A per ounce daily. The local treatment included warm irrigations with a 1 to 6,000 solution of metaphen every three hours during the day, drops of 1 per cent atropine solution three times a day and 1 to 5,000 mercurial ointment instilled at bedtime; in addition, hot applications were given to the left eye for twenty minutes every three hours.

By the third hospital day the patient began to have pain in the left eye and the discharge from both had markedly increased; this marked the turning point. Two days later the discharge and pain had subsided and the corneas had regained their luster and their normal sensitivity. White sclera showed through at the periphery, and the swelling of the bulbar conjunctiva had receded so that the left cornea appeared nearly normal in relief. By the eighth day the hypopyon had completely disappeared and the ulcerated area was devoid only of epithelium. The whitish plaques in the mouth had disappeared.

During the following ten days the patient again became worse; the discharge increased and became more purulent; superficial ulceration was noted on the right cornea and the old area on the left eyeball again became active. Typhoid vaccine was given intravenously; the response was excellent. Within three days the corneal surfaces had healed and the associated ciliary injection had completely disappeared. A second dose of vaccine was given at this time and on the following day, February 27, all the patient's teeth were extracted. By March 1 the eyeballs were white and free of congestion; the corneal surfaces were intact. He left the hospital March 11, completely recovered but with considerable and permanent damage to the eyes.

PERMANENT CONDITION OF EYES

The palpatory tension of the right eye was normal. The conjunctiva was normal except near the edge of the lower lid, where it was moderately thickened. All but a triangular segment of the corneal surface at its upper extremity, comprising one sixth of its area, was covered by a nebulous opacity. The surface was unbroken but very irregular and covered with many minute facets where the scarring was more pronounced. There were four superficial capillaries at equal intervals extending half way from the limbus to the center of the cornea. Under dilation with atropine the pupil was 3 by 4 mm. wide and the lower two thirds of its circumference was attached to the lens. It was filled with a meshwork of pigment and fine white strands of old exudate through the intervals of which a red reflex, but no fundus markings, could be defined. The vision was 20/100.

The tension of the left eye was normal. The upper tarsal conjunctiva was moderately scarred but smooth; the conjunctiva near the lower lid margin was moderately thickened. Two superficial capillaries, one above and one below, extending two thirds of the distance to the center, marked the temporal border of a flattened macular scar that covered three fifths of the nasal side of the cornea. The remaining two fifths was clear except near the limbus, where the surface was faintly mottled. Under dilation with atropine the pupil was 2.5 mm. wide. It was filled with a network of pigment interwoven with a thin layer of organized exudate. All but a 1 mm. segment, of the inferior temporal portion of the pupillary border was incarcerated in this curtain. This segment formed a rounded indentation 1 mm. wide in the iris margin, through which a bright red reflex was seen. A less brilliant reflex was obtained through other intervals in the pupillary network. No fundus markings could be defined. The vision was 20/100.

COMMENT

Although hemeropia is a frequent symptom in the ordinary, mild, chronic, adult type of xerophthalmia, it was not present at any time in this case. The disease ran a protracted course for six years, with a seasonal variation in severity. During the fall and winter months the patient consumed no vitamin A, while in the spring a few green vegetables and eggs became timely sight-savers. The effect of abundant sunlight, as proved by the ingenious experiments of Powers, Park and Simmonds,⁹ must also have been an important seasonal therapeutic factor.

Clinical Notes, Suggestions and New Instruments

A METHOD OF ROENTGEN LOCALIZATION OF FOREIGN BODIES IN THE STOMACH PRIOR TO GASTROSCOPIC REMOVAL

GABRIEL TUCKER, M.D., PHILADELPHIA

The roentgen localization of foreign bodies in the stomach has offered considerable difficulty. When a foreign body is shown in the upper part of the abdomen, the proof as to whether it is in the stomach, the transverse colon or the small intestine

A, anteroposterior view showing rubber tube (R. T.) passing through the hiatal esophagus and curling round the greater curvature of the stomach, coming in contact with the piece of wire (W) in front of the spine. B, lateral view showing the rubber tube (R. T.) passing through the hiatal esophagus, coming in contact with the wire (W). The localization in both planes definitely shows the foreign body in the stomach and its relation to the hiatal esophagus. Roentgenograms by Drs. Pancoast and Pendergrass.

is sometimes quite difficult to obtain. The usual method is the preparation of films in the anteroposterior and lateral planes, which are of considerable value. The administration of an opaque mixture, which passes through the esophagus and immediately comes in contact with the foreign body, will usually give definite information. It is a disadvantage, however, if gastroscopic removal under fluoroscopic guidance is to be made, as it is necessary to wait for the opaque mixture to pass out of the stomach and upper part of the abdomen before fluoroscopic guidance can be satisfactorily given in many cases.

In a recent case in which there was a piece of wire supposed to be in the stomach, it was desired to localize it definitely and at the same time show its relation to the cardiac

9. Powers, G. F.; Park, E. A., and Simmonds, Nina: Influence of Radiant Energy upon Development of Xerophthalmia in Rats, *J. Biol. Chem.* 55: 575 (April) 1923.
From the Bronchoscopic Clinic of the Hospital of the University of Pennsylvania.

end of the stomach and the hiatal esophagus. In order to do this the patient swallowed a rubber tube, which passed through the hiatal esophagus and cardia, coiling itself round the greater curvature of the stomach, giving its relation to the foreign body in the anteroposterior and lateral planes. The foreign body was definitely localized in the stomach and at the same time its relation to the hiatal esophagus was shown, as seen in the accompanying illustration. The tube was also used to empty the stomach before gastroscopy. If it was desired, air could also be insufflated into the stomach through the tube before its withdrawal.

COMMENT

In a new method of localization of foreign body in the stomach, a rubber tube of the Levin or Weiss type feeding tube is passed and allowed to remain in position during the making of films, the patient being placed in the position required for gastroscopy. The advantages of this method are:

1. It shows the location of the foreign body with reference to the tube that is passed into the stomach.
2. The tube stays in the lower part of the esophagus and cardiac end of the stomach and gives a definite localization of the foreign body to the cardiac end of the stomach, where the gastroscope is to be introduced.
3. The rubber tube is withdrawn and gastroscopic removal can be proceeded with immediately.
4. The stomach contents can be aspirated and air introduced if desired before the tube is withdrawn.

236 South Nineteenth Street.

FATALITY RESULTING FROM THE USE OF LASH-LURE ON THE EYEBROW AND EYELASHES

S. B. FORBES, M.D., AND W. C. BLAKE, M.D., TAMPA, FLA.

During the past twelve months, instances of dermatoconjunctivitis due to the use of eyelash and eyebrow dyes have been reported by Greenbaum,¹ Harner,² Bourbon,³ Jamieson,⁴ McCally, Farmer and Loomis,⁵ and Moran.⁶ In the cases reported by the last two the reaction was severe enough to produce ulceration and necrosis of the cornea. Six of the reported cases were due to the use of the preparation "Lash-Lure," and two followed the use of "Godefroy French Hair Coloring"—Larieuse.

The case reported here followed immediately the use of "Lash-Lure" and terminated fatally.

REPORT OF CASE

A woman, aged 52, who had considered herself in good health, had her right eyebrow "plucked" and the dye "Lash-Lure" applied to the right brow and eyelashes. This was done by her daughter, an employee of a beauty parlor. The adjacent tissues began to burn and swell within thirty seconds after the application of the dye. The pain was so severe that the operator decided not to treat the left eyebrow. Within a few hours the patient felt ill and the tissues around the eye were so swollen that she was unable to open her eye. The following day her temperature was said to be 104 and she consulted a physician who gave her a mixed streptococcus and staphylococcus vaccine and applied wet dressings of magnesium sulphate. The inflammatory reaction of the right side of the face extended and the temperature ranged between 102 and 104. Wet dressings of boric acid were used and ointment of yellow mercuric oxide was instilled in the conjunctival sac.

The patient was seen by us for the first time during the evening of March 13, 1934, eight days after the onset. On

examination at 8 p. m., the patient appeared to be extremely ill. The temperature was 103.4, pulse 134, respiration 36. She was clear mentally and did not complain of pain, but she said that she felt completely exhausted. The skin over the right side of the forehead and cheek was red but not tense and glistening. The upper lid of the right eye was covered with a deep sloughing ulcer with much yellowish adherent exudate.

The palpebral conjunctiva of the upper and lower lids showed complete ulceration of a deep character. The conjunctival sac was filled with a yellowish, tenacious exudate that could be removed only with difficulty. As this exudate was removed, a bleeding base was left on the ulcerative areas on the inner surfaces of the lids.

There was some injection of the globe, and the ocular conjunctiva was slightly chemotic. The cornea was hazy in sort of a striped manner, but no real break could be made out after using fluorescein. The pupils were equal and reacted consensually to light and in accommodation. The eyegrounds were negative in the left eye. It was impossible to examine the fundus

Fig. 1.—Appearance post mortem of large sloughing ulcer. The anterior cervical glandular enlargement is well shown.

of the right eye. There was no apparent proptosis of the right eye. The preauricular glands were palpable. The lymph glands on the right side of the neck in the anterior region, particularly just below the mandible, were greatly enlarged, as is shown in figure 1. The nose, throat and teeth were normal.

The area of cardiac dullness was within normal limits, sounds were clear and no murmurs were heard. The rhythm was normal, the rate 136, the blood pressure 114 systolic, 76 diastolic. Respiration was rapid and somewhat shallow. There was no odor of acetone. The percussion note was everywhere resonant, breath sounds were roughened, but no râles were heard on quiet breathing or following expiratory cough. The abdomen was entirely negative on palpation except for what appeared to be an ovarian cyst on the right side about the size of a grapefruit, which was not tender on pressure. There was no edema of the dependent parts or the extremities. All superficial and deep reflexes were moderately exaggerated. Kernig and Babinski's signs were negative and there was no neck rigidity. Aside from the face and neck the skin was clear, there being no evidence of petechiae, purpura or urticaria.

5. McCally, A. W.; Farmer, A. G., and Loomis, E. C.: Corneal Ulceration Following Use of Lash-Lure, J. A. M. A. 101:1560 (Nov. 11) 1933.

6. Moran, C. T.: Bilateral Necrosis of the Cornea Following the Use of Hair Dye on the Eyebrows and Lashes, J. A. M. A. 102:286 (Jan. 27) 1934.

The lashes of the right eye were clipped and potassium permanganate irrigations and hot compresses were used. Atropine and mercuric oxycyanide instillations were also used. The patient failed to respond to general supportive measures such as digifolin and hypodermoclysis, and died at 11:30 p. m., just three hours after our first examination. No autopsy could be obtained.

COMMENT

It is with some hesitation that we report this case, owing to lack of laboratory data. A conjunctival culture was made, which showed a pure growth of *Staphylococcus aureus*. Blood counts and blood cultures were ordered, but the patient died before the specimens could be obtained.

The active principle in "Lash-Lure" is an aniline dye, the members of this group being capable of producing a violent allergic response in susceptible individuals. Plucking the eyebrow before application would furnish multiple portals of entry for the dye equivalent to multiple skin tests applied to a small area. There is no doubt that the patient's illness was brought about as a violent local and systemic allergic response. It is

Fig. 2.—The condition of the palpebral conjunctiva on the two lids was the same. This shows only the sloughing ulcer on the under surface of the upper lid.

not clear, however, why this should have caused death eight days later unless a secondary septic invasion, probably some form of streptococcus, is assumed. The appearance in no way suggested erysipelas, and there was no evidence of cavernous sinus thrombosis or involvement of the nervous system.

With the growing evidence to show the disastrous effects resulting from the application of "Lash-Lure" and similar aniline dye preparations in "beauty treatments," some way should be found to prevent their use.

Pathology of the Myopathies.—The recent discovery of Sir Henry Dale that efferent stimuli in the vegetative nervous system produce their effect by the liberation of a chemical intermediary of the choline group, and that stimulation of the sympathetic in otherwise denervated skeletal muscle results in tonic contraction, seems to me to open up the possibilities of great advance in our very scant knowledge of the pathology of the myotonias, myasthenias and myopathies.—Collier, James: The Harveian Oration on "Inventions and the Outlook in Neurology," *Brit. M. J.* 2:707 (Oct. 20) 1934.

DYSPNEA

CLINICAL LECTURE AT CLEVELAND SESSION

J. C. MEAKINS, M.D.

MONTREAL

The science of clinical medicine rests on the knowledge of the causes of symptoms and signs and the interpretation of their functional significance. This holds equally valid whether applied to the diagnosis, prognosis or treatment of disease. Symptoms as a rule are a personal prerogative of the patient, while signs are discovered by the physician. There are exceptions to this statement, but these emphasize its general truth. Since an individual considers himself in good health until something arises which interferes with or embarrasses his capacity for work or pleasure, it is therefore a symptom or symptoms which usually first induce him to seek medical advice. Such sensations or symptoms are the first manifestations of disordered or embarrassed function and frequently are complained of before anatomic changes are detectable. Thus it is obvious that they are of the utmost importance. Sir James Mackenzie, one of the greatest clinicians of the past generation and the father of modern clinical cardiology, was firmly convinced that medical research had too long neglected the investigation of the early symptoms and during the latter years of his life devoted his energies to their elucidation. He was particularly interested in the significance and mode of production of visceral discomfort and pain. There is no doubt that the greatest symptom of all is pain in its varying characters, intensities and localizations. It may be called *the* symptom of localization.

But little inferior to pain in symptomatic importance is dyspnea. Some years ago I defined it as follows: "Dyspnea is the consciousness of the necessity for increased respiratory effort." Although this symptom is referred to the respiratory system, its causation is not confined by any means to pulmonary lesions. Whereas pain is chiefly a local phenomenon, dyspnea is broadly systemic and there is practically not one of the great systems which, when disturbed after a certain manner, may not produce a respiratory consciousness. It is with these respiratory disturbances, the mode of their production, and their clinical significance that I wish to deal here.

REGULATION OF RESPIRATION

Ordinarily in the healthy individual respiration is an unconscious function, although it can be modified at will. With these voluntary modifications the present discussion is not concerned. A short review of the unconscious or spontaneous act of respiration is, however, essential.

The rhythmic inflation and deflation of the lungs, which produces pulmonary ventilation, must be able to accommodate itself to great changes at short notice. This is done in the first instance by increasing or decreasing the volume of each respiration and later, if necessary, by an acceleration or diminution in the rate. The turnover from inspiration to expiration is brought

From the Department of Medicine, McGill University Clinic, Royal Victoria Hospital.

Read before the General Scientific Meeting at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 12, 1934.

about by what is commonly called the Hering-Breuer reflex. I shall not enter into the pros and cons that have given rise to a controversy about this reflex but will merely state that it is supposed to depend on variations in tension of the alveolar wall. As the lungs are inflated by inspiration the tension increases to a certain point, when the reflex turns inspiration to expiration. The pathway for the afferent impulses is through the vagus, while the efferent impulses pass by way of the phrenic and spinal nerves. A mechanism such as described would be automatic but rigid unless some means were at hand to vary the points at which the reflex reversal took place. There is strong evidence to suggest that in the midbrain (anatomically vague but physiologically fairly definite) there is an area called the respiratory center, which initiates the respiratory rhythm and controls the points of the reflex. This center is in its turn responsive to its own hydrogen ion concentration, which is one of the most constant of the internal equilibria. If this increases or becomes more acid, the points of the Hering-Breuer reflex become farther apart and respiration deepens in volume and increases in rate; if it decreases or becomes more alkaline the points approximate and respirations become more shallow and slower until they may finally cease.

It is quite apparent from this short description that the control of respiration depends on two factors, one chemical, the other nervous. It is not within the scope of the present paper to deal in detail with the hydrogen ion control of the blood and tissues, but the rôle of carbon dioxide cannot be omitted. It may be stated in brief that the kidneys are the principal organs that maintain the gross hydrogen ion equilibrium, but it remains for the lungs to control the finer variations through their elimination or retention of carbon dioxide. The vast majority of substances that influence the reaction of the blood and tissues diffuse quite slowly in and out of cells, while carbon dioxide is very soluble and readily diffusible. Therefore, although it is a weak acid, it is ideal for the finer regulation of the acid base equilibrium of the body. If for any reason the tissues, including the respiratory center, tend to an increase of hydrogen ions, the respiratory center through its nervous control of the Hering-Breuer reflex and of the respiratory muscles (diaphragm and intercostals) increases the pulmonary ventilation, which in turn augments the elimination of carbon dioxide, which reduces the hydrogen ion concentration of the blood and, in turn, of the tissues, thus helping to restore the normal internal environment. The opposite occurs when the hydrogen ion concentration decreases; then pulmonary ventilation is reduced. At times, respiration struggles against an increasingly impossible task, as in untreated diabetic acidosis or the profound and increasing alkalosis of intractable vomiting.

The respiratory center is also sensitive to changes in oxygen tension. If for any reason an adequate supply of oxygen is not furnished to the respiratory center, it is more sensitive to its normal or increased hydrogen ion concentration. This reduction in oxygen supply may be due to a number of causes: (1) imperfect aeration of the blood as it passes through the lungs, (2) a deficiency of hemoglobin, as in anemias, or (3) a reduced total blood flow or a local slowing of blood flow through the respiratory center.

It is obvious, then, that dyspnea can be produced by either increased acidity or decreased oxygenation of the respiratory center. But there is also a local pulmonary

factor, which has probably not received sufficient recognition in the past but which may be of profound significance in the genesis of dyspnea. The primary stimulus of the Hering-Breuer reflex is the tension change in the lung parenchyma that occurs on inflation, and any condition, such as pulmonary engorgement, that decreases the distensibility of the lung will exaggerate the excitability of this reflex. In other words, any condition that increases the rigidity of the lung will tend to produce rapid and shallow breathing with dyspnea. If the nervous and clinical control of respiration as outlined is intact and in normal equilibrium, respiratory consciousness should not be present under all conditions of rest and work appropriate to the individual's age and training.

Before proceeding to deal individually with different pathologic conditions, I will state that dyspnea is quantitative. Any one can become short of breath under given conditions of exercise, even the perfect athlete. Further, advancing years reduce one's capacity for physical work, but dyspnea is not really abnormal unless it is produced by conditions that are less than would be expected for the average individual, taking into consideration his age and manner of life. Dyspnea that would be considered abnormal in a youth might be quite well expected in an octogenarian. In progressive states dyspnea will be first noticed on exertion and as the cause increases the margin of activity will become more

and more limited until there is respiratory consciousness even during complete rest. Therefore, dyspnea is not only a qualitative but also a quantitative symptom of comparative accuracy.

Numerous attempts have been made to correlate the degree of dyspnea with various measurements, such as the vital capacity and the ventilation equivalent. Any such correlation has been shown to be thoroughly untrustworthy. However, when one comes to analyze the lung volume and its subdivisions in greater detail, it can be shown that the degree of respiratory impairment is directly proportional to the ratio of the functional residual air to total capacity of air or, more simply expressed, the ratio of the amount of air normally in the lungs to the volume of air in the lungs on full inspiration. Time does not permit of entering into a discussion of the real meaning of this ratio; suffice it to say that under average normal conditions it lies between 3 and 4 to 10 and that, as this ratio approaches unity, dyspnea becomes more and more intense. The measurement of this ratio is of especial significance in the estimation of the disability resulting from silicosis and other forms of pulmonary fibrosis.

In table 1 there is a brief but, I believe, comprehensive synopsis of the causes of dyspnea. It is true that there may be a number of variants of each of these causes. These may be produced by different means, but the end result will be in general the same. In order that a more detailed outline may be afforded, I have grouped them under principal systems. This grouping

may seem arbitrary at times but it has the advantage of brevity and also I believe of clarity.

The exact nature of the substances causing the acidosis in uremia and prostatism is not stated. It would be beyond the scope of the present paper to enter into a discussion of these. Furthermore, in certain cases of

TABLE 2—*Metabolic Disturbances*

Disease or Condition	Stimulus	Type of Breathing	Treatment
Exercise	Carbon dioxide excess	Full and deep	Physical training
Diabetes	Ketosis (acetoacids)	Full and deep	Insulin and carbohydrates
Nephritis, uremia	Acidosis	Full and deep (Cheyne Stokes)	Treat nephritis
Prostatism	Acidosis	Full and deep	Relieve urinary retention
Hyperthyroidism	Carbon dioxide excess, sympathetic ?	Full and deep	Iodine or operation
Insulin shock	Low blood pressure, sinus carotidæ ?	Rapid and shallow	Carbohydrates

diabetes, terminal nephritis and prostatism, circulatory complications either as associated lesions or due to age may exert a powerful influence in producing dyspnea when the acidosis may be mild or absent. The more

TABLE 3—*Pulmonary Diseases*

Diseases or Condition	Stimulus	Type of Breathing	Treatment
Laryngeal or bronchial obstruction	Carbon dioxide retention, oxygen want	Forceful inspiration and ineffective expiration	Removal of obstruction
Asthma	Carbon dioxide retention, oxygen want, later loss of elasticity	Forceful inspiration and ineffective expiration	Epinephrine, epedrine and desensitization
Emphysema	Loss of elasticity and sensitivity of Hering-Breuer reflex	Forceful inspiration and ineffective expiration	Abdominal binder to support diaphragm in expiration
Pneumonoconiosis	Loss of elasticity and sensitivity of Hering-Breuer reflex ?	Forceful inspiration and ineffective expiration	Abdominal binder to support diaphragm in expiration
Lobar pneumonia	Pulmonary congestion and sensitivity of Hering-Breuer reflex	Rapid and shallow	Treat pneumonia specifically, continuous oxygen therapy if there is cyanosis; artificial pneumothorax ?
Massive collapse	Pulmonary congestion and sensitivity of Hering-Breuer reflex	Rapid and shallow	Artificial pneumothorax; carbon dioxide therapy
Infarction	Pulmonary congestion, sensitivity of Hering-Breuer reflex and low blood pressure (see shock)	Rapid and shallow	Treatment of the shock
Bronchopneumonia	Pulmonary congestion, sensitivity of Hering-Breuer reflex, low blood pressure, carbon dioxide retention, oxygen want	Rapid and shallow	Continuous oxygen therapy if cyanosis is present

one tries to analyze and reduce to simple statements the pathologic physiology of dyspnea, the more one encounters lesions in which there is a summation of the possible causes that may operate in varying degrees in different cases.

In obstruction, asthma, emphysema and probably pneumonoconiosis, the functional disturbances of respiration are chiefly inherent in the difficulties of expira-

tion. Inspiration is accomplished by the action of a strong muscular mechanism. Expiration is ordinarily a passive act furthered by the negative intrapleural pressure, but in those conditions due to the loss of elasticity it is transformed into an active function producing a positive intrapleural pressure, which in time undoubtedly will be harmful to the return flow of the venous blood.

Furthermore, in these conditions the lungs are almost in a state of full expansion when inspiration is initiated, therefore a greater physical effort is demanded to expand the inelastic lung still farther. It has been found that the functional residual air in these conditions is greatly increased, while the total capacity is unchanged or decreased. Therefore, instead of the ratio of the functional residual air to the total capacity

TABLE 4—*Circulatory Diseases*

Diseases or Condition	Stimulus	Type of Breathing	Treatment
Cardiac Mitral disease	Pulmonary engorgement, sensitivity of Hering-Breuer reflex	Rapid and shallow	Treatment of cardiac function and pulmonary engorgement; abdominal binder
Congestive cardiac failure	Pulmonary engorgement, sensitivity of Hering-Breuer reflex, central anoxemia ? carbon dioxide retention	Rapid and shallow	Treatment of cardiac function and pulmonary engorgement; abdominal binder, oxygen therapy if cyanosis relieved, venesection for increased venous pressure
Myxedema	Pulmonary engorgement, sensitivity of Hering-Breuer reflex	Rapid and shallow	Treatment of hypothyroidism with caution
Coronary lesions	Chronic: pulmonary engorgement, sensitivity of Hering-Breuer reflex. Acute: shock, low blood pressure (see shock)	Rapid and shallow Rapid and shallow	Oxygen therapy if cyanosis relieved, venesection for increased venous pressure; treatment of shock
Peripheral Hypertension	Pulmonary engorgement, later central anoxemia ?	Rapid, with tendency to Cheyne Stokes	Treatment of pulmonary engorgement as above
Renal hypertension	Pulmonary engorgement, later central anoxemia ?	Rapid, with tendency to Cheyne Stokes	Treatment of pulmonary engorgement as above
Arteriosclerosis without hypertension	Pulmonary engorgement, later central anoxemia ?	Rapid, with tendency to Cheyne Stokes	Treatment of pulmonary engorgement as above
Anemias	Oxygen want ?; muscular weakness ?; congestive failure ?	Rapid and shallow	Treatment of anemia

being about 0.4 (4 to 10), it is between 0.7 and 0.8 (7 or 8 to 10). This would have but little effect in the normally elastic lung but in these cases in which the elasticity is so greatly reduced and proper ventilation grossly impaired, it contributes to the difficulty of gaseous exchange and thus accentuates the dyspnea.

The interaction of different causes of dyspnea in disturbances of circulation makes the untangling of the different factors somewhat difficult to express in general terms. The degree of each functional disturbance varies from case to case and from time to time in the same case. There are in these cases four possible factors: pulmonary engorgement leading to hypersensitivity of the Hering-Breuer reflex; arterial anoxemia due to faulty pulmonary aeration; central anoxemia due to arterial anoxemia or due to slowing of the general blood flow or to a local arterial lesion as in advanced

stages of essential hypertension, renal hypertension or arteriosclerosis without hypertension. Absolute proof is wanting that there is a reduction in the oxygen consumption of the brain in severe cases with dyspnea and orthopnea; in fact, all evidence suggests the contrary but it also strongly indicates that the higher centers are enduring a lower partial pressure of oxygen. This would be equally so whether there was an arterial anoxemia, a general slowing of the blood flow or local slowing due to arterial disease. Increasing venous pressure would tend to aggravate these conditions and there seems little doubt that orthopnea is an attempt to compensate for this. The dyspnea of anemia is probably also due to a combination of several factors, of which oxygen want due to the reduced amount of hemoglobin to carry oxygen is probably the most important, as it would not only affect the respiratory center itself but lead to impairment of myocardial as well as respiratory efficiency.

Among the nervous disorders are grouped a miscellaneous collection of conditions, some of which may

TABLE 5.—*Nervous Disorders*

Diseases or Condition	Stimulus	Type of Breathing	Treatment
Cerebral Traumatic (edema or hemorrhage)	Stimulus to respiratory center	Deep and slow; deep and rapid; periclude	Relief of Intra-cranial tension
Tumors	Stimulus to respiratory center	Deep and slow; deep and rapid; periclude	Relief of Intra-cranial tension
Postencephalitic	Stimulus to respiratory center ?; psychic ?	Paroxysmal	? (Treatment of psychosis if present)
Psychic	Anxiety neurosis	Rapid, shallow and irregular	Treatment of primary cause
	Conversion hysteria	Rapid, deep and irregular	Treatment of primary cause
Shock	Low blood pressure; sinus caroticus ?	Rapid and shallow	Treatment of primary cause
Respiratory paralysis			
(a) Nerve	Mechanical	Rapid and shallow	Treatment of primary cause
(b) Muscular			
Abdominal distention	Mechanical	Rapid and shallow	Treatment of primary cause
Thoracic pain	Reflex inhibition of movement	Rapid and shallow	Treatment of primary cause

not rightly belong there but for the sake of conciseness are included. Probably the most interesting and the least recognized are those due to psychic causes. They are much commoner than is usually appreciated and often lead to mistakes in diagnosis. Their outstanding character is the irregularity of the respirations both in depth and in rate and the tendency to paroxysmal outbursts.

A few words must here be given to the dyspnea that occurs in various conditions of visceral shock such as occurs with coronary and pulmonary infarction, renal and gallbladder colic and Dietl's crises. The dyspnea in all these conditions appears to be intimately associated with the fall of blood pressure, and there is much to suggest that the sinus caroticus is in the same manner responsible for the respiratory disturbance.

I have attempted in the short time at my disposal to give a bird's eye view of this rather large subject. I have tried to leave out nothing of importance and at the same time not to baffle with too much detail the practical importance of dyspnea or consciousness of respiration. There are many knots still to be unraveled and, as it is the most important of the early symptoms of systemic disease, continued endeavors will be well rewarded.

REPORT OF THE COMMITTEE ON DEFINITION OF BLINDNESS

Your committee was appointed in response to a request from the Department of Public Welfare of the State of Illinois for a definition of blindness, in scientific terms, that might be made statutory. Such a definition should be brief, definite and comprehensive. It cannot include and settle all the problems that grow out of blindness. It cannot radically alter the meaning generally attached to a word that has been widely used by many people over a long period of time. It can be made practical only by recognizing that blindness varies in degree, and the resulting disabilities must be broadly implied by the use of auxiliary words to indicate conditions that can be generally recognized. Your committee is indebted to the Report on Definition of Blindness compiled by the Bureau of Legal Medicine and Legislation of the American Medical Association in October 1933.

To give effect to the report of your committee it must be considered and discussed in the Section on Ophthalmology, and, when agreed to by the section, the endorsed definitions must be transmitted to the House of Delegates for its approval. The rules of the House of Delegates prevent the introduction of new business on the last day of the annual meeting.

The definition of a word is fixed by usage. Blindness has been so widely used by people who had no exact knowledge of what they meant by it that it cannot be restricted to a sharply defined impairment to vision.

The makers of dictionaries, from studies of the use of words, have come to general agreement in their definitions of blindness. The Oxford Dictionary gives: blind, "destitute of the sense of sight"; blindness, "blind condition, want of sight." The Standard Dictionary, "the state or condition of being blind." The Century, blindness, "want of sight." The International, "state or quality of being blind." Gould's Medical Dictionary, "deprived of sight, want of vision."

The general disposition to help the blind requires definitions that can be applied by legislation, appealed to in the courts, and serve for purposes of justice and in decisions as to insurance and workmen's compensation. Definitions agreed on and understood by ophthalmologists are useful, although they need to be embodied in special legislative acts designed to help the blind. In the Blind Persons Act of Great Britain the definition used is "One so blind as to be unable to perform any work for which eyesight is essential." For the "Education Act" the blind are those "too blind to be able to read the ordinary school books."

The public needs to know that poor vision of different kinds and degrees is worthy of legal recognition. In a broad way, visual acuity of less than one tenth may be recognized as economic blindness. Equal disability from restriction of the visual field may demand the same recognition. There is a series of disabilities for seeing that extends from full vision to complete blindness. No definition can draw a rigid line between vision and blindness that shall apply to all persons and all kinds of visual impairment. It will clear away some confusion to insist that questions of the existence and degree of blindness must be passed on in each particular case by some one accustomed to study and treat the diseases of the eye.

We recommend the adoption of the following definitions for grades of blindness:

Total blindness is inability to perceive light; lack of light perception. The person who is totally blind cannot tell whether strong light falls on his eyes or whether they are in total darkness. Light perception is vision such as one has when the eyelids are closed.

Economic blindness is absence of ability to do any kind of work, industrial or otherwise, for which sight is essential. In general, visual acuity of less than one tenth has been classed

as economic blindness, meaning that objects can be recognized only when brought within one tenth of the distance at which they can be recognized with standard vision. Such vision in the better eye when corrected with the best possible glass would be recorded as less than 0.1 or 6/60 or 20/200, or as an equally disabling loss of the visual field.

Vocational Blindness is impairment of the vision that makes it impossible for a person to do work at which he had previously earned a living. He may still have vision enough to do some other kind of work that may yield him an adequate support. Such vision in the better eye with the best possible correcting glass may vary from one tenth to one third; that is, from 0.1 or 6/60 or 20/200 to 0.3 or 6/18 or 20/60, depending on the vision required for the occupation previously followed.

Educational blindness is such loss of sight as makes it difficult, dangerous or impossible to learn by the methods that are commonly used in schools. This necessitates two types of schooling for such individuals; namely, sight saving classes and schools for the blind. The requirement for admission to sight saving classes is vision in the better eye with the best possible correcting glass of less than 20/70 and more than 20/200.

The requirement for admission to the school for the blind is vision in the better eye, with the best possible correcting glass, of 0.1 or 6/60 or 20/200 or less.

Respectfully submitted.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED.

THERAPY OF BURNS

It is necessary to distinguish between (a) burns of limited extent, (b) infected burns, and (c) extensive burns.

In all cases of deep burns a prophylactic dose (1,500 units) of tetanus antitoxin should be administered.

FRESH (ASEPTIC) BURNS OF LIMITED EXTENT

Fresh (aseptic) burns of limited extent require protection against infection and relief of the burning pain.

(a) Sodium bicarbonate, made into a thick paste with water, applied thickly and kept in place with a sterile bandage, is probably the best domestic emergency

PRESCRIPTION 1.—Trinitrophenol Solution

R Trinitrophenol 10.00 Gm.
Alcohol 100.00 cc.
Sterile water to make 1,000.00 cc.

M. Label: Apply on compress to burns of limited extent. This solution may be kept on hand.

application. A change of dressing is indicated by the appearance of a discharge on the outer covering.

(b) In using a trinitrophenol (picric acid) compress (prescription 1), one should soak a sterile gauze pad

in the solution, cover by a dry gauze pad, and bandage lightly, distended blisters having previously been punctured in an aseptic manner. Rubber gloves should be worn to prevent staining of the hands. In superficial burns the original dressing may be left on until complete healing has taken place. A dressing may be changed as often as required by a discharge commencing to appear at the surface of the dressing, maybe every two or three days. If the previous dressing sticks, it may be softened by moistening with the same solution. This dressing must not be used on extensive burns because of the danger of poisoning.

PRESCRIPTION 2.—Gentian Violet Jelly

R Gentian violet..... 1.00 Gm.
Tragacanth (tears)..... 3.00 Gm.
Sterile water..... 100.00 cc.

Make into a jelly. Label: Apply a thick layer on gauze pad; cover with dry gauze pad and sterile dressing.

(c) Gentian violet jelly (prescription 2) is claimed to be superior to any of the foregoing because it is antiseptic, analgesic and nontoxic and produces a thin, light eschar, qualities not presented thus combined in any of the others.

INFECTED BURNS

When, by reason of improper previous treatment, infection has occurred with excessive and offensive discharge, foul sloughs and inflammation spreading into surrounding tissue, cleansing must be done by irrigation with Surgical Solution of Chlorinated Soda and loose sloughs must be removed with forceps and scissors. Such treatment should be repeated daily, and during the intervals hot boric acid dressings, large enough to extend way beyond the limit of redness, should be applied so as to provoke reactionary hyperemia in surrounding tissue to check the spread of the infection. These dressings should be changed at first often enough to keep them hot; i. e., at least every two hours day and night. As soon as spreading of infection has been checked, they need not be applied as hot and should be changed merely often enough to keep them moist; i. e., every four hours.

When the infection has been "cleaned up," the raw surface is treated in accordance with the principles of ulcer therapy (q. v.).

EXTENSIVE BURNS

Extensive burns threaten life in proportion to the surface area involved.

1. Shock (q. v.) is treated by absolute recumbency, warmth, morphine sulphate 0.015 Gm. hypodermic injection, pushing of fluids by all available channels, aiming at from 4 to 8 liters in the twenty-four hours, antagonizing hypochloridation by Physiologic Solution

PRESCRIPTION 3.—Ether Soap

R Soft soap..... 300.00 Gm.
Alcohol 200.00 cc.

Mix and allow to stand for 24 hours; decant from sediment and add Ether..... enough to make 1,000.00 cc.

Label: Ether Soap. (Useful preoperative detergent, especially for removal of all kinds of fatty material.)

of Sodium Chloride and acidosis by the administration of dextrose phlebotomy. Early blood transfusion may save life. As soon as the symptoms of shock abate, the next step may be taken.

2. The wound is cleansed, best with ether soap (prescription 3), if fatty material has been previously applied, and in a general warm (100 F.) bath if the

involvement is very extensive, débridement being employed to remove all undoubtedly dead tissue.

3. A "cradle tent" is placed over the patient, who is to lie in it, without clothing or dressing, on a sterile sheet with the most affected body surface uppermost. Enough incandescent electric lights (maybe four or six) are permitted to burn within the "tent" to maintain a temperature of about 85 F.

4. Coagulation of dead surface cells should be undertaken as promptly as possible, for every hour's delay endangers life.

PRESCRIPTION 4.—Normal p_H Tannic Acid Solution

R Tannic acid.....	50.00 Gm.
Anhydrous sodium carbonate.....	7.95 Gm.
Sterile water.....	to make 1,000.00 cc.

M. (Must be freshly prepared.)

Label: Spray with atomizer over affected surface every fifteen to thirty minutes.

(a) Tannic acid solution 5 per cent must be freshly prepared when used. For this purpose 5 Gm. packages of tannic acid should be kept on hand, one of which may be dissolved in 100 cc. of sterile water. Tannic acid solution of normal (7.4) p_H value (prescription 4) might be preferable. The solution is sprayed on every fifteen to thirty minutes to form a good coagulum within the first twenty-four hours, after which no further application is necessary for several days, unless blisters form. These should be opened with sterile scissors, the loose outer layer of epidermis removed, and the tannic acid solution applied as before. When, by the sixth to the eighth day, exudate begins to form beneath the crusts, especially if symptoms of sepsis appear, the fluctuating areas are incised and compresses of Surgical Solution of Chlorinated Soda are applied to dissolve and remove the dead tissue and to secure a clean granulating surface.

(b) Gentian violet in 1 per cent solution sprayed on the burned area every two hours is claimed to form a tough but more elastic eschar, which being antiseptic inhibits germ growth, which is likely to destroy the small epithelial islands that may have been spared by the burn and that are responsible for the septic temperature so prone to develop after the first few days under the tannic acid treatment. After a good eschar is formed, the area is sprayed every four to six hours during the day. Blebs are opened and the unstained tissue thus exposed is sprayed with the dye solution. The eschar is examined daily for softened areas, which must be removed by picking up with forceps, after which the surface is again sprayed with the dye. The eschar, which acts as a scaffolding to the healing process, curls up at the periphery, whereupon it should be trimmed away to prevent the formation of pockets, which might become infected. By the third week the eschar should be removed by means of warm compresses of sterile physiologic solution of sodium chloride and it will be ready for the next step:

5. Skin grafting (see Ulcer Therapy) or other methods of plastic surgery should not be postponed until crippling contractures have developed; and their establishment should even prior to this be antagonized by posturing the involved area so as to prevent the formation of flexure deformities.

6. The general care of the patient may require, in addition to maintaining optimal nutrition, analgesia (see Therapy of Pain), fever regimen (q. v.) and the securing of an abundance of sleep (see Insomnia).

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.
H. A. CARTER, Secretary.

FACTORS INFLUENCING THE CHOICE OF A SOURCE OF RADIANT ENERGY

(ULTRAVIOLET, LUMINOUS AND INFRA-RED)

HENRY LAURENS, PH.D.
NEW ORLEANS

The number of diseases or of abnormal conditions really or primarily benefited by sunlight is small in comparison with the enormous number for which such claims have been made by manufacturers and clinicians. A recent report of the Council on Physical Therapy of the American Medical Association¹ bears testimony to this.

No one now doubts that sunlight represents one of the benefits of an outdoor life, that it is one of the things that make for physical and mental well being, that in extrapulmonary tuberculosis it confers immeasurable benefit, that in rickets certain wavelengths are specific; but there is still a strong tendency to exaggerate the vital importance of sunlight (natural and artificial) and to make extravagant claims for it as a therapeutic force. Certain diseases and disabilities are partly due to deficient radiation of various kinds, and doubtless the health of the community may be improved by providing more radiation where sunlight does not reach the small minimum required for health; but sunlight is only one of the many environmental factors that affect vitality.

On the face of it, it would seem a simple matter to select an artificial source of radiant energy (ultraviolet, luminous and infra-red energy). This is true, however, only for experienced physical therapists, and particularly those who have made some special study of this branch or subdivision of physical therapy. The average physician, on the other hand, knows little or nothing about the characteristics of natural sunlight, and less about the "artificial sunshine" emitted by lamps. A perusal of the literature put out by many manufacturers only confuses him, if he reads it literally, with its claim of simulating the sunlight of the High Alps or of some other geographic area. There is, of course, no source of radiant energy that does this, although it is closely approximated by a carbon arc, consuming 25 amperes or more, burning specific carbons, such as the "Sunshine" carbons.

The energy emitted by various artificial sources varies in intensity and in spectral distribution. The intensity of solar radiation (sunlight) on the earth's surface varies considerably, chiefly on account of location, season and time of day. The sun itself is a variable star, the total amount of radiation that it emits varying by as much as 5 per cent. Furthermore, the amount of radiation that reaches the earth's surface is greatly dependent on changes in atmospheric transparency occasioned, for example, by smoke, water vapor and dust.

as economic blindness, meaning that objects can be recognized only when brought within one tenth of the distance at which they can be recognized with standard vision. Such vision in the better eye when corrected with the best possible glass would be recorded as less than 0.1 or 6/60 or 20/200, or as an equally disabling loss of the visual field.

Vocational Blindness is impairment of the vision that makes it impossible for a person to do work at which he had previously earned a living. He may still have vision enough to do some other kind of work that may yield him an adequate support. Such vision in the better eye with the best possible correcting glass may vary from one tenth to one third; that is, from 0.1 or 6/60 or 20/200 to 0.3 or 6/18 or 20/60, depending on the vision required for the occupation previously followed.

Educational blindness is such loss of sight as makes it difficult, dangerous or impossible to learn by the methods that are commonly used in schools. This necessitates two types of schooling for such individuals; namely, sight saving classes and schools for the blind. The requirement for admission to sight saving classes is vision in the better eye with the best possible correcting glass of less than 20/70 and more than 20/200.

The requirement for admission to the school for the blind is vision in the better eye, with the best possible correcting glass, of 0.1 or 6/60 or 20/200 or less.

Respectfully submitted.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED.

THERAPY OF BURNS

It is necessary to distinguish between (a) burns of limited extent, (b) infected burns, and (c) extensive burns.

In all cases of deep burns a prophylactic dose (1,500 units) of tetanus antitoxin should be administered.

FRESH (ASEPTIC) BURNS OF LIMITED EXTENT

Fresh (aseptic) burns of limited extent require protection against infection and relief of the burning pain.

(a) Sodium bicarbonate, made into a thick paste with water, applied thickly and kept in place with a sterile bandage, is probably the best domestic emergency

PRESCRIPTION 1.—Trinitrophenol Solution

R Trinitrophenol 10.00 Gm.
Alcohol 100.00 cc.
Sterile water.....to make 1,000.00 cc.
M. Label: Apply on compress to burns of limited extent. This solution may be kept on hand.

application. A change of dressing is indicated by the appearance of a discharge on the outer covering.

(b) In using a trinitrophenol (picric acid) compress (prescription 1), one should soak a sterile gauze pad

in the solution, cover by a dry gauze pad, and bandage lightly, distended blisters having previously been punctured in an aseptic manner. Rubber gloves should be worn to prevent staining of the hands. In superficial burns the original dressing may be left on until complete healing has taken place. A dressing may be changed as often as required by a discharge commencing to appear at the surface of the dressing, maybe every two or three days. If the previous dressing sticks, it may be softened by moistening with the same solution. This dressing must not be used on extensive burns because of the danger of poisoning.

PRESCRIPTION 2.—Gentian Violet Jelly

R Gentian violet..... 1.00 Gm.
Tragacanth (tears)..... 3.00 Gm.
Sterile water..... 100.00 cc.
Make into a jelly. Label: Apply a thick layer on gauze pad; cover with dry gauze pad and sterile dressing.

(c) Gentian violet jelly (prescription 2) is claimed to be superior to any of the foregoing because it is antiseptic, analgesic and nontoxic and produces a thin, light eschar, qualities not presented thus combined in any of the others.

INFECTED BURNS

When, by reason of improper previous treatment, infection has occurred with excessive and offensive discharge, foul sloughs and inflammation spreading into surrounding tissue, cleansing must be done by irrigation with Surgical Solution of Chlorinated Soda and loose sloughs must be removed with forceps and scissors. Such treatment should be repeated daily, and during the intervals hot boric acid dressings, large enough to extend way beyond the limit of redness, should be applied so as to provoke reactionary hyperemia in surrounding tissue to check the spread of the infection. These dressings should be changed at first often enough to keep them hot; i. e., at least every two hours day and night. As soon as spreading of infection has been checked, they need not be applied as hot and should be changed merely often enough to keep them moist; i. e., every four hours.

When the infection has been "cleaned up," the raw surface is treated in accordance with the principles of ulcer therapy (q. v.).

EXTENSIVE BURNS

Extensive burns threaten life in proportion to the surface area involved.

1. Shock (q. v.) is treated by absolute recumbency, warmth, morphine sulphate 0.015 Gm. hypodermic injection, pushing of fluids by all available channels, aiming at from 4 to 8 liters in the twenty-four hours, antagonizing hypochloridation by Physiologic Solution

PRESCRIPTION 3.—Ether Soap

R Soft soap..... 300.00 Gm.
Alcohol 200.00 cc.
Mix and allow to stand for 24 hours; decant from sediment and add Ether.....enough to make 1,000.00 cc.
Label: Ether Soap. (Useful preoperative detergent, especially for removal of all kinds of fatty material.)

of Sodium Chloride and acidosis by the administration of dextrose phleboclysis. Early blood transfusion may save life. As soon as the symptoms of shock abate, the next step may be taken.

2. The wound is cleansed, best with ether soap (prescription 3), if fatty material has been previously applied, and in a general warm (100 F.) bath if the

involvement is very extensive, débridement being employed to remove all undoubtedly dead tissue.

3. A "cradle tent" is placed over the patient, who is to lie in it, without clothing or dressing, on a sterile sheet with the most affected body surface uppermost. Enough incandescent electric lights (maybe four or six) are permitted to burn within the "tent" to maintain a temperature of about 85 F.

4. Coagulation of dead surface cells should be undertaken as promptly as possible, for every hour's delay endangers life.

PRESCRIPTION 4.—Normal p_{H} Tannic Acid Solution

R Tannic acid.....	50.00 Gm.
Anhydrous sodium carbonate.....	7.95 Gm.
Sterile water.....	to make 1,000.00 cc.

M. (Must be freshly prepared.)

Label: Spray with atomizer over affected surface every fifteen to thirty minutes.

(a) Tannic acid solution 5 per cent must be freshly prepared when used. For this purpose 5 Gm. packages of tannic acid should be kept on hand, one of which may be dissolved in 100 cc. of sterile water. Tannic acid solution of normal (7.4) p_{H} value (prescription 4) might be preferable. The solution is sprayed on every fifteen to thirty minutes to form a good coagulum within the first twenty-four hours, after which no further application is necessary for several days, unless blisters form. These should be opened with sterile scissors, the loose outer layer of epidermis removed, and the tannic acid solution applied as before. When, by the sixth to the eighth day, exudate begins to form beneath the crusts, especially if symptoms of sepsis appear, the fluctuating areas are incised and compresses of Surgical Solution of Chlorinated Soda are applied to dissolve and remove the dead tissue and to secure a clean granulating surface.

(b) Gentian violet in 1 per cent solution sprayed on the burned area every two hours is claimed to form a tough but more elastic eschar, which being antiseptic inhibits germ growth, which is likely to destroy the small epithelial islands that may have been spared by the burn and that are responsible for the septic temperature so prone to develop after the first few days under the tannic acid treatment. After a good eschar is formed, the area is sprayed every four to six hours during the day. Blebs are opened and the unstained tissue thus exposed is sprayed with the dye solution. The eschar is examined daily for softened areas, which must be removed by picking up with forceps, after which the surface is again sprayed with the dye. The eschar, which acts as a scaffolding to the healing process, curls up at the periphery, whereupon it should be trimmed away to prevent the formation of pockets, which might become infected. By the third week the eschar should be removed by means of warm compresses of sterile physiologic solution of sodium chloride and it will be ready for the next step:

5. Skin grafting (see Ulcer Therapy) or other methods of plastic surgery should not be postponed until crippling contractures have developed; and their establishment should even prior to this be antagonized by posturing the involved area so as to prevent the formation of flexure deformities.

6. The general care of the patient may require, in addition to maintaining optimal nutrition, analgesia (see Therapy of Pain), fever regimen (q. v.) and the securing of an abundance of sleep (see Insomnia).

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.
H. A. CARTER, Secretary.

FACTORS INFLUENCING THE CHOICE OF A SOURCE OF RADIANT ENERGY

(ULTRAVIOLET, LUMINOUS AND INFRA-RED)

HENRY LAURENS, Ph.D.
NEW ORLEANS

The number of diseases or of abnormal conditions really or primarily benefited by sunlight is small in comparison with the enormous number for which such claims have been made by manufacturers and clinicians. A recent report of the Council on Physical Therapy of the American Medical Association¹ bears testimony to this.

No one now doubts that sunlight represents one of the benefits of an outdoor life, that it is one of the things that make for physical and mental well being, that in extrapulmonary tuberculosis it confers immeasurable benefit, that in rickets certain wavelengths are specific; but there is still a strong tendency to exaggerate the vital importance of sunlight (natural and artificial) and to make extravagant claims for it as a therapeutic force. Certain diseases and disabilities are partly due to deficient radiation of various kinds, and doubtless the health of the community may be improved by providing more radiation where sunlight does not reach the small minimum required for health; but sunlight is only one of the many environmental factors that affect vitality.

On the face of it, it would seem a simple matter to select an artificial source of radiant energy (ultraviolet, luminous and infra-red energy). This is true, however, only for experienced physical therapists, and particularly those who have made some special study of this branch or subdivision of physical therapy. The average physician, on the other hand, knows little or nothing about the characteristics of natural sunlight, and less about the "artificial sunshine" emitted by lamps. A perusal of the literature put out by many manufacturers only confuses him, if he reads it literally, with its claim of simulating the sunlight of the High Alps or of some other geographic area. There is, of course, no source of radiant energy that does this, although it is closely approximated by a carbon arc, consuming 25 amperes or more, burning specific carbons, such as the "Sunshine" carbons.

The energy emitted by various artificial sources varies in intensity and in spectral distribution. The intensity of solar radiation (sunlight) on the earth's surface varies considerably, chiefly on account of location, season and time of day. The sun itself is a variable star, the total amount of radiation that it emits varying by as much as 5 per cent. Furthermore, the amount of radiation that reaches the earth's surface is greatly dependent on changes in atmospheric transparency occasioned, for example, by smoke, water vapor and dust.

From the Laboratory of Physiology, Tulane University of Louisiana School of Medicine.

1. Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession Only, J. A. M. A. 102:841 (March 17) 1934.

The use of radiant energy (natural or artificial sunshine) for therapeutic or scientific purposes must be built on a strong foundation of physics, and users of lamps, since they are essentially trying to imitate sunlight and its effects, must know something about the physics of their sunlight. They certainly should know how much, or approximately how much, energy (expressed in ergs, gram calories or microwatts) the patient is getting, and the distribution of this energy; that is to say the percentage of the total energy that is ultraviolet, luminous and infra-red.

The radiations of artificial sources represent but approximations to sunlight and no two sources are alike in respect to the distribution of the energy they emit. This is the physical reason why different sources cannot produce the same physiologic or therapeutic action. Every one using artificial sunlight should realize this and not be misled into believing that the energy emitted by this, that or the other lamp represents "artificial sunlight" when in many cases it is as far from that as it can possibly be.

The variations in the intensity of the energy actually emitted by the sun are the result of either long period fluctuations, due to changes in solar activity, or of short period fluctuations, due to obscurations in the solar atmosphere which, rotating with the sun, produce depressions whenever they point toward the earth. The variations in total solar energy influence particularly the ultraviolet. For instance, with a range of only 2.3 per cent in total energy the ultraviolet at 3,500 angstroms² shows a variation of about 30 per cent and much more at and shorter than 3,100 angstroms—the antirachitic region.

At the surface of the earth with the sun moderately high and a total radiation intensity of 1 gram calory per square centimeter per minute (70,000 microwatts per square centimeter) and 1.5 gram calories per square centimeter per minute (105,000 microwatts per square centimeter), the percentage of the ultraviolet is between 1 and 5, the luminous between 41 and 45, and the infra-red between 52 and 60. When the sun is lower (i. e., farther from the zenith) the ultraviolet is decreased and the infra-red increased. At high altitudes above sea level the percentage of ultraviolet increases at the expense of the infra-red. The total energy, of course, is also greater than at sea level. Only about 75 per cent of the sun's energy penetrates as low as 1,800 meters and only 50 per cent to sea level, and this on the clearest days and when the sun is high. The seasonal variation in the shortest ultraviolet wavelength getting through to the earth's surface at midday is about 120 angstroms (from 2,970 to 3,090 angstroms) and the diurnal variation ranges between 60 angstroms in winter (from 3,060 to 3,120 angstroms) and 240 angstroms in summer (from 2,960 to 3,200 angstroms). Summer midday sun is only 10 per cent richer in the infra-red than is winter sun, in the red 45 per cent, in the green 90 per cent, in the blue-violet 250 per cent, and in the ultraviolet 1,000 per cent. Spring sunlight is the strongest and richest in infra-red, the autumn sun, by comparison, being richer in ultraviolet, the maximum content of which is reached in the summer.

The shortest wavelength that gets through the atmosphere to the earth depends on solar altitude; e. g., at Davos, Switzerland (1,560 meters), with the sun 30 degrees above the horizon the shortest wavelength

recorded was 3,043 angstroms, while at 60 degrees it was 2,979 angstroms.

Solar radiation is often described as extending from 3,000 angstroms to 3 microns.³ On the long waved side there is a small amount of radiation as long as 5 microns, and traces beyond that, but less than 1 per cent is longer than 3 microns. And on the short-waved side it is only on days of exceptional clearness and purity of the atmosphere that any wavelengths shorter than 3,000 angstroms penetrate to sea level. In New Orleans, for instance, on only one day since the beginning of 1928 has the wavelength 2,990 angstroms been recorded. During the winter months the spectrum rarely extends below 3,060 angstroms, except on very clear days. From June 1 to Dec. 31, 1929, only three days showed limits shorter than 3,040 angstroms; only five days in 1930 and only twelve days from January to August 1931. Air pollution, clouds and haze decrease the extent of the spectrum, so that even in August the spectrum does not often extend below 3,100 angstroms. Measurements made in Chicago showed that there was comparatively little ultraviolet radiation of wavelengths shorter than 3,030 angstroms from December to March. On the other hand, it has been demonstrated in many cities (New York, Boston, Toronto, New Brunswick, Ithaca, New Orleans) that winter sunshine is antirachitic; that is to say, it contains a sufficiently large proportion of wavelengths shorter than 3,130 angstroms to cure and prevent rickets.

It is of interest to remember that in all there are six principal causes of variation in solar radiation intensities at the surface of the earth: (1) variations in the amount of energy radiated from the sun, (2) variations in the earth's solar distance, (3) amount of water vapor in the atmosphere, (4) dustiness or haziness of the atmosphere, (5) zenith distance of the sun, and (6) altitude above sea level.

The hemispherical dome of the sky may be compared to the sun as a source of radiant energy. Skylight is nothing more than sunlight scattered by the atmosphere. The scattering is inversely proportional, in a perfectly dry dust-free atmosphere, to the fourth power of the wavelength, and therefore ultraviolet is relatively much more increased in scattered daylight than in direct sunlight.

On a clear summer day at places up to about 1,560 meters above sea level the total diffuse radiant energy from the sky is between 12.5 and 33⅓ per cent of the total, and at midday the radiation received on a horizontal surface from the sky averages 25 per cent of that received from the sun. At Davos, Switzerland (1,560 meters), on a perfectly clear day the sun accounts for 88.5 per cent and the sky for 11.5 per cent of the luminous rays incident on a horizontal surface.

At New Orleans at noon on clear days the sky contributes between 7 and 17 per cent of the total (sun and sky) radiation. The presence of clouds increases considerably the percentage of the total contributed by the sky; e. g., on April 24, 1931, sky radiation at noon composed 31 per cent of the total (sun and sky) radiation.

The spectrum of the ultraviolet radiation from the sky ends approximately just where that of the sun does. At Davos, Switzerland, the values for the ultraviolet shorter than 3,660 angstroms received directly from the sun are hardly 90 per cent of those from the sky alone. At higher altitudes above sea level this does not hold

2. The angstrom unit of wavelength is one ten-millionth millimeter.

3. The micron is one one-thousandth millimeter.

for solar altitudes above 40 degrees, the sun being then a more powerful source of ultraviolet than is the sky.

It is strange, in the light of such facts, to consider how much importance is attached to exposure to direct sunshine. Of course, when such exposure is made, radiation is being received from both the sun and the sky; but, so far as the ultraviolet is concerned, the sky alone is a more potent source than is the sun alone.

According to careful measurements the total amount of ultraviolet radiation of wavelengths less than 3,100 angstroms in sunlight is extremely small. Coblentz and Stair in 1929 concluded that even on the clearest days at the noon hour in summer such energy at the most amounted to only 0.3 per cent of the total incident radiation (or about 0.004 gram calory, or 280 microwatts), and more likely only one tenth of this value at sea level stations. The so-called average value, which would be much lower, depends on the condition of the sun, the altitude and latitude of the station, and the almost infinite variety of air pollution and weather conditions that are encountered at different seasons of the year and during different years. In New Orleans, Laurens and Mayerson find that the maximum ultraviolet of wavelengths shorter than 3,100 angstroms on clear days approximates 0.001 gram calory per square centimeter per minute (70 microwatts).

Greider and Downes found the percentage of the total radiation between 2,900 and 3,100 angstroms at the Springfield Lake Sanatorium, near Akron, Ohio, and at Cragmor Sanatorium, near Colorado Springs, Colorado, to be of the order of 0.01 and 0.02 and on Mount Wilson (1,750 meters) about 0.1. At Davos (1,650 meters) the ultraviolet between 2,900 and 3,100 angstroms is 0.4 per cent of the total ultraviolet and at the two sanatoriums mentioned by Greider and Downes it is between 0.6 and 0.7 per cent. Pettit deduced that on Mount Wilson the intensity of the ultraviolet component of wavelengths 2,900 to 3,100 angstroms in midsummer sunlight amounts to about 70 microwatts per square centimeter (0.001 gram calory per square centimeter per minute). This amounts to 90 microwatts per square centimeter (0.00129 gram calory per square centimeter per minute) for wavelengths 2,900 to 3,130 angstroms. Coblentz and his co-workers now believe that the average amount of ultraviolet solar radiation of wavelengths shorter than 3,130 angstroms for mid-latitude sea level stations during the clearest weather during midday in midsummer is about 90 microwatts (0.00129 gram calory), decreasing to about 20 microwatts (0.000285 gram calory) on the clearest days in midwinter.

CHOICE OF SOURCE

In many places the intensity of sunlight varies too much or is too weak for too great a proportion of the time to permit of its being a practical source of radiant energy. In the choice and use of an artificial source, there are two basic considerations: (1) the physical nature (quantity and quality) of the energy emitted by the lamp; (2) the specific part or parts of the spectrum of sunlight found most efficient in the particular condition it is desired to alleviate or aid and which should thus be sought in sufficient quantity in the artificial radiation.

There is a general, almost universal, but wrong, tendency to limit the biologic effects of radiant energy and their therapeutic action to the ultraviolet and particularly to the region between 2,900 and 3,130 angstroms. That radiation is solely or mainly active because

of the ultraviolet fraction has been unequivocally demonstrated in only a few instances (rickets and infantile tetany). There is considerable evidence on the other hand that the luminous and infra-red rays, even if not specific in their action, aid the ultraviolet rays.

At the Finsen Light Institute in Copenhagen it is believed that the sun is unquestionably the best of all sources of radiant energy, where and when it is available, and that the best artificial source is to be decided on the basis of the similarity of its spectrum to that of the sun or as to its content of those rays which typify the therapeutic action of sunlight.

On the basis of the quality of ultraviolet wavelengths and of the results obtained at the seashore, at sea level inland and in the mountains, Strandberg of the Finsen Institute believes that energy of wavelengths 3,130 angstroms and longer is the region of influence in the treatment of extrapulmonary tuberculosis. Therefore, if one is forced to use artificial energy instead of sunlight, one should choose a type of lamp which, like the sun, exhibits a continuous spectrum and possesses the greatest number of blue, violet and longer, rather than shorter, ultraviolet rays, as well as luminous and near infra-red rays. Phelps at New Haven agrees with Strandberg, but his method of demonstration did not exclude the presence and action of wavelengths shorter than 3,130 angstroms.

Bernhard, at St. Moritz, in the treatment of wounds of all sorts, uses sunlight as such, without concentrating the ultraviolet or filtering out the infra-red. He firmly believes that the benefits observed are due to the penetrating wavelengths (between the green-yellow and shorter infra-red). This is borne out by the poor results on wound healing exerted by "ultraviolet rays" emitted by a mercury vapor arc in quartz.

It has been abundantly demonstrated that the luminous and infra-red rays emitted by tungsten lamps or parlor or bathroom electric heaters are of value in conditions requiring deep action, as in the relief of pain in sprains, fractures, pulled tendons, bruised muscles, and so on, rather than the ultraviolet.

It is clear that under different conditions all parts of the radiant energy spectrum will yield results, if particular conditions demand the wavelength a particular source emits strongly. But clinicians interested in this branch of physical therapy should know what they are doing, what wavelengths they are using, the total intensity of the energy emitted, and its percentage spectral distribution. This they should do in preference to describing as "ultraviolet" the total radiation from a lamp, of inconsiderately ascribing to the "ultraviolet" all the effects produced, and of speaking of all sources of radiant energy as "ultraviolet" sources or generators, when they emit at the same time much greater quantities of luminous and infra-red rays.

For therapeutic purposes the sun, the mercury vapor arc in quartz and the flaming carbon arc burning cored carbons filled with mixtures of carbon dust and metals have been the only ones of practical importance. The "Sunlight" lamps or "Sunlamps" developed by the General Electric Company are a combination of a mercury vapor arc in special ultraviolet transmitting glass bulbs (Corex D) and a tungsten arc. At the bottom of the glass bulb is a little pool of mercury. When the lamp is turned on, a V-shaped tungsten filament glows and the heat vaporizes the mercury so that an arc forms between two tungsten electrodes. Eighty-one and eight-tenths per cent of the energy comes from the electrodes,

1.7 per cent from the filament and the remainder from the arc.

The General Electric Mazda Sunlight Lamp S-2 is smaller and less expensive than the S-1. Its ultraviolet output is also somewhat less, but by exposing the skin at a shorter distance from the lamp (24 inches) the biologic effectiveness equals that of the type S-1 lamp at 30 inches.

The mercury vapor lamp used to deteriorate very rapidly, but its length of useful life has been markedly increased in recent years, so that the physician may expect a useful life of between 2,500 and 3,000 hours. The deterioration, when the lamp is properly treated, is due to changes in the quartz, making it less transparent. When the lamp is improperly operated and cleaned, the deterioration is more rapid and particularly affects the emission of the ultraviolet for which, so far as the physician is concerned, the mercury vapor lamp in quartz has been particularly developed, the ultraviolet component representing between 9 and 28 per cent of the total energy of all wavelengths emitted by the lamp.

Coblentz, Dorcas and Hughes, several years ago, made a comparison of the distribution of the radiation

a distribution of 4 per cent ultraviolet, 9 per cent luminous and 87 per cent infra-red.

One of the National Carbon Company's Professional Model A-1 carbon arc lamps has been in use in my laboratory for about eighteen months. With 25 amperes flowing through the arc, the total energy emitted is 0.320 gram calory per square centimeter per minute incident at a meter (22,400 microwatts), with a distribution of 6 per cent ultraviolet, 50 per cent luminous and 44 per cent infra-red. With a Corex D screen, which eliminates by absorption the short ultraviolet and the long infra-red rays not found in sunlight, the total energy emitted is 0.287 gram calory (20,090 microwatts), and its distribution 5 per cent ultraviolet, 62 per cent luminous and 33 per cent infra-red.

When therapeutic "C" carbons are burned in this lamp the total energy emitted has a value of 0.266 gram calory (18,620 microwatts), with a distribution of 9 per cent ultraviolet, 24 per cent luminous and 67 per cent infra-red.

The point of these details is to emphasize the close similarity between the energy emitted by a carbon arc lamp, when operated on an appropriate amperage and burning "Sunshine" carbons, to sunlight. Compare the values for a Hanovia air cooled mercury lamp with a distribution (as given by the company) of 28 per cent in the ultraviolet, 20 per cent in the luminous and 52 per cent in the infra-red; and of an old Cooper Hewitt air-cooled quartz mercury lamp in my laboratory with a total energy output, when operated at between 4 and 5 amperes, of between 0.0562 and 0.0619 gram calory per square centimeter per minute incident at a meter and with a distribution of 13 per cent ultraviolet, 7 per cent luminous and 80 per cent infra-red.

In connection with the Sunlight Lamp of the General Electric Company, Taylor gives the following values for the distribution of the energy in terms of percentage of total from shortest wavelength to 7,400 angstroms: from shortest to 4,000 angstroms = 5.05; from 4,000 to 7,400 angstroms = 7.80, the remainder, or 87.15 per cent, being infra-red.

These lamps have been shown to be capable of curing rickets when weekly erythema doses were given. They were developed, however, for "dual lighting" for illumination and health. This purpose does not seem to have been realized and in my opinion never will be.

If penetrating rays are desired, there is no use to look further than a 500 watt gas-filled tungsten lamp. The total energy emitted approximates that of sunlight. The shorter wavelengths can be screened out by a sheet of red glass, and the longer by a water cell or a sheet of Corning G-392-H (heat absorbing) glass. Such a source has found usefulness in conditions in which deep action has been desired, as in sprains, fractures or bruised muscle. Similar results are obtainable with the carbon arc burning "Sunshine" carbons and using screens to cut out the ultraviolet and longer infra-red, which would produce surface action and thus limit the time during which application could be made, owing to ultraviolet erythema and the prickling, burning pain of the longer infra-red rays.

The ordinary quartz mercury arc is of the low voltage type, in which the incandescent column of mercury carries a relatively high current, amounting to 4 or more amperes, or from 400 to 600 watts in the burner. The temperature and vapor pressure are relatively high and the ultraviolet radiation is contained principally in the intense emission lines at 2,540, 2,800, 2,970, 3,020, 3,130, 3,340 and 3,650 angstroms.

of various lamps and that of the sun. The accompanying table illustrates their results.

A carbon arc lamp ("Pan-Ray" of the Atlas Electric Devices Company of Chicago), which has been in use for eight years in my laboratory, emitted when new (1926) about 1 gram calory per square centimeter per minute incident at 1 meter (70,000 microwatts). In 1928 this had diminished to 0.797 (55,790 microwatts), in 1929 to 0.747 (52,290 microwatts), in 1930 to 0.721 (50,470 microwatts), in 1931 to 0.571 (39,970 microwatts), in 1932 to 0.449 (31,430 microwatts), and in 1933 to 0.447 (31,290 microwatts). This diminution in total intensity is due to deterioration of the reflector surfaces. These values are for the "Sunshine" carbon (one-half by 12 inches) when the lamp is operated at between 25 and 28 amperes. The distribution in 1929 was 6 per cent ultraviolet (shorter than 4,000 angstroms), 31 per cent luminous (4,000 angstroms to 1.4 microns) and 63 per cent infra-red (longer than 1.4 microns); in 1933, 4 per cent ultraviolet, 35 per cent luminous and 61 per cent infra-red.

When this lamp is burning the therapeutic "C" carbons, the total energy emitted is 0.441 gram calory per square centimeter per minute (30,870 microwatts), with

The "cold quartz" mercury vapor lamp has a low vapor pressure, a low amperage (0.015) and a high potential (5,000 volts, open circuit) glow discharge. There is no great rise in the temperature of the burner, because the power consumed is small (about 75 watts in the primary of the transformer, and only about 8 to 10 watts in the lamp). About 95 per cent of the radiation of wavelengths less than and including 3,130 angstroms is emitted in the resonance line at 2,537 angstroms. Coblenz reports that in the emitted energy from a "cold quartz" official applicator the 2,540 angstrom line had an intrinsic intensity of 215 microwatts per square centimeter (0.00307 gram calory per square centimeter per minute) at the surface of the applicator; further, that the relative intensities of the short wavelength ultraviolet lines at 3,130, 2,970 and 2,540 angstroms were 45, 14 and 865. The total radiation of wavelengths less than and including the line at 3,130 angstroms at a distance of 25 cm. from the lamp was 186 microwatts per square centimeter (0.002657 gram calory per square centimeter per minute).

The total energy of one of the official applicator type lamps measured in my laboratory by a thermopile method was found to be 0.0018 gram calory per square centimeter per minute (126 microwatts per square centimeter) at a distance of 1 meter from the lamp, as compared with 0.0619 gram calory per square centimeter per minute (4,333 microwatts per square centimeter) for the old Cooper Hewitt high temperature lamp.

An important question is the minimum ultraviolet radiant flux (radiant power) that a source must emit in order to insure effective therapeutic action. The amount of ultraviolet radiation that can be applied to the body without producing a burn depends on the tolerance of the skin. This can be measured by the erythema produced, specifically a mild or "minimum perceptible erythema," or one that disappears in the course of twenty-four hours. The spectral erythemic reaction is produced only by ultraviolet rays of wavelengths shorter than about 3,150 angstroms with a maximum reaction at the wavelength 2,967 angstroms and a lesser maximum percentage in the region of 2,500 angstroms. The midday, midlatitude, sea level ultraviolet in summer sunshine with an intensity of from 80 to 90 microwatts per square centimeter produces a minimum perceptible erythema in from twenty to forty-five minutes, depending on the person. In winter the intensity is only about 20 microwatts (on the clearest days at noon) and the time is lengthened to from three to five hours. Forenoon and afternoon summer sunlight has an average intensity of 30 microwatts per square centimeter.

The intensity (radiant flux) from sources of heterogeneous ultraviolet radiation of wavelengths less than and including 3,130 angstroms, evaluated according to the spectral erythemic response curves, should not be less than the equivalent of 20 microwatts (200 ergs, 0.000285 gram calory) per square centimeter of homogeneous radiation of the wavelength of maximum erythrogenic effectiveness, which wavelength for practical purposes is taken at the emission line of mercury vapor 2,967 angstroms.

Although there is no close relationship between the spectral erythemic response and the therapeutic action of radiant energy, the erythemic reaction is taken as a criterion for judging the effectiveness of a lamp for three reasons: (a) It is practically the only physiologic

reaction that is established with a relatively high degree of accuracy; (b) in the case of exposure to intense sources of ultraviolet radiation, it is a simple and practical means of preventing severe burns, and (c) in the case of weak sources of ultraviolet radiation it is an efficient safeguard against possible fraudulent sale of lamps that are deficient in ultraviolet radiation. The ultraviolet radiant flux emitted by the present-day "professional models" of the various kinds of therapeutic lamps greatly exceeds this specific minimum value.

Some sort of standardization of measurement and of dosage is needed in order that results may be compared. The specification may be in terms of (a) radiant power in microwatts per square centimeter or (b) total energy in ergs per square centimeter. The total energy must be ascertained by a nonselective method that can be calibrated in absolute units (thermopile and galvanometer), as must the homogeneous erythemogenic radiation of wavelength 2,967 angstroms employed as a standard. Coblenz⁴ has worked out a suggestion for a unit based on the comparison between the erythema produced by measured amounts of heterogeneous ultraviolet radiation evaluated by a balanced thermocouple and filter radiometer. In this evaluation the erythema produced by a measured amount of homogeneous radiation of wavelength 2,967 angstroms is used as a standard. For the various sources of heterogeneous ultraviolet radiation of wavelengths less than and including 3,130 angstroms the erythemogenic equivalent of 20 microwatts (0.000285 gram calory) per square centimeter of homogeneous radiation of wavelength 2,967 angstroms in microwatts per square centimeter is approximately as follows: the sun at midday, midsummer, midlatitude, sea level, 91; the Mazda S-1 lamp, 80; the Mazda S-2 lamp, 93; the high temperature quartz mercury arc, 58; the so-called cold quartz mercury vapor lamp, 36; the carbon arc, from 45 to 90 (estimated, depending on electric current, kind of carbons and windows); and the Mazda CX tungsten filament lamp, 130 (estimated).

At the specified operating distance of from 2½ to 3 feet (75 to 90 cm. approximately) the ultraviolet radiant flux from these various artificial sources equals or exceeds the specified minimum values, in all cases excepting the 500 watt Mazda CX lamp. These lamps (Mazda tungsten filament) are not suitable sources of ultraviolet radiation for therapeutic purposes, although they may be used when penetration to subcutaneous regions is desired. At convenient operating distances (30 inches, or 80 cm.) they cause profuse sweating, which is an objectionable feature in general body irradiation. This can be avoided by using a source that emits a high intensity of the short wavelength ultraviolet radiation relative to the total emitted by the lamp and reflector. This permits operating the lamp at a sufficient distance from the patient and yet obtaining an effective dose of ultraviolet radiation.

It is becoming more and more evident that, aside from knowing whether a lamp emits sufficient ultraviolet energy to be of clinical value (specification of minimum intensity of ultraviolet radiation necessary to insure effective therapeutic action) and knowing about how long an irradiation with it will produce a desired degree of erythema, a dosage meter in practical heliotherapy has no value. The individual patient is the

4. Coblenz, W. W.: Ultraviolet Radiation Useful for Therapeutic Purposes, *J. A. M. A.* **98**: 1082 (March 26) 1932; **99**: 125 (July 9) 1932; Report to the Council on Physical Therapy on Heliotherapy Methods in Some European Sanatoriums, *ibid.* **100**: 410 (Feb. 11) 1933.

important consideration, how he reacts, favorably or unfavorably, and the dosage modified accordingly.

The Council on Physical Therapy accepts only the products of companies whose claims do not exceed the performance of the generators described. No lamp should be purchased either for office or for hospital use until it is ascertained whether or not it has been "Council accepted." The physician has a wide choice: carbon arcs, quartz mercury vapor lamps, both in office models and solarium or group models, "cold quartz" lamps, "sunlamps" and infra-red lamps, according to his needs and the physics of the energy emitted and the therapeutic indication.

It is not out of place to call attention again to the fact that the number of human ills and abnormalities for which radiant energy, as emitted by the sun, carbon arcs and quartz mercury vapor lamps, is specific or adjuvant is small, much smaller than the number for which claims are made by manufacturers, as well as by members of the medical profession.

Ultraviolet rays (shorter than 3,130 angstroms) are specific in the cure and prevention of rickets (infantile and adult) and infantile tetany. Such wavelengths are not always available in sunshine, and recourse to artificial sources is frequently necessary. The quartz mercury vapor lamp, the "Sunlamp" and the carbon arc (either "Sunshine" or "C" carbons) yield more than enough of these rays.

Cases of extrapulmonary tuberculosis (including lupus vulgaris) are markedly benefited by careful exposure to sunlight (Rollier at Leysin and Lausanne) or to the closest approximation to natural sunlight; viz., the energy emitted by a carbon arc lamp (Finsen Institute at Copenhagen). The benefits, I am convinced, are due not solely to ultraviolet rays, either those specific in rickets or somewhat longer, but as well to the light or luminous rays and to the heat or infra-red rays, which are so preponderantly present in natural sunshine and carbon arc radiation. The reports of the results with the quartz mercury vapor lamp in the treatment of extrapulmonary tuberculosis are disappointing.

Natural sunlight will hasten the healing of sluggish, indolent wounds, as was demonstrated so clearly by Oskar Bernhard at St. Moritz. This effect, however, is certainly not a specific effect of short ultraviolet rays. The effect is a deep one and is brought about by wavelengths that penetrate through the epidermis and part of the dermis. The effect is an indirect one through the circulation, as Torraca demonstrated. The surface action of ultraviolet wavelengths shorter than 2,900 or of those slightly longer (up to 3,100) in large quantity is detrimental to the healing of wounds, unfavorably influencing the processes of repair. The influence is due to longer ultraviolet, luminous and infra-red rays, and so the quartz mercury vapor lamp is not indicated while natural sunshine and the energy from "Sunshine" carbons are.

Ultraviolet rays alone do not lower the blood pressure, but carbon arc radiation ("Sunshine" carbons) does—that is to say, of a certain percentage (between 60 and 70) of persons with abnormally high blood pressure. I have shown in both ambulatory and hospitalized patients that both systolic and diastolic pressure may be materially reduced (from 10 to 15 per cent) by general carbon arc irradiation, given in erythema-producing doses, not too frequently repeated, so as to avoid tanning. The "cure" is temporary, and the treat-

ments have to be repeated, being given every ten days or two weeks in those whose pressures have been lowered by earlier more often repeated large doses (usually every fourth or fifth day).

There are many substances and proprietary preparations that have been introduced for the purpose of lowering blood pressure. As Sir Thomas Lewis puts it, none have come to be regarded as reliable or even as offering much or any prospect of benefit. Perhaps the most striking reflection on their value is the short period of popularity that each enjoys. The amount by which pressure is lowered by these remedies is not usually great and the fall is either transient or restricted to the period of the drug's administration. There is no known method of lowering pressure materially and over long periods of time; the most effective treatment is a suitably restful regimen.

I believe, because I have demonstrated it, that carbon arc radiation in large enough doses to set up an inflammatory reaction, accompanied by marked vasodilatation, not too frequently repeated, so as to avoid pigmentation, will produce a 10 to 15 per cent reduction in both systolic and diastolic pressures. The mercury vapor lamp in quartz will not do this and the effect is thus not the specific effect of ultraviolet rays but of these and, in addition, the luminous and infra-red, as emitted by "Sunshine" carbons.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
GENERAL DECISION. RAYMOND HERTWIG, Secretary.

ENERGY CLAIMS FOR FOODS

All foods except the simple mineral foods and water contain chemical energy available for use by the healthy body to support the many activities and life processes and incidentally to maintain temperature. This use of the term "energy" in defining the caloric energy value of foods should not be confused with the popular usage signifying the state of extreme well being, good health, vitality, strength, vigor or endurance. These conditions depend on many factors, including freedom from disease, native constitution, physical environment, good general nutrition, wholesome life habits and others. Even good nutrition, a necessity for health, requires far more than available food-energy only; all the nutritional essentials of a complete, well balanced diet, in adequate amounts, are demanded.

Food advertising should correctly inform the public of the energy values of foods in carefully chosen terms that may be properly interpreted. The distinction between the caloric and popular senses of the word "energy" must be recognized and observed.

Examples of appropriately phrased food-energy claims are: "Good source of food-energy," "High in food-energy content," "Furnishes (x) calories of food-energy per ounce of food," "Provides food-energy for supporting energy demands of the body for work and play," "Furnishes food-energy for replenishing the energy losses of any physical work." Misinformative uses not correctly interpretable by the public and fostering deceptive advertising are exemplified by the statements: "Energy food," "Gives energy," "Furnishes energy for pep and vitality," "For quick energy," "For reviving or renewing energy." Illustrations representing vigorous muscular activity accompanying misinformative energy claims accentuate the unwarranted implications.

The terms "food value" or "nutritional value" should not be used synonymously with "food-energy value." The food or nutritional value of a food includes the vitamin, mineral, protein, fat, and other values.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

CALIFORNIA PRUNES EDUCATIONAL
ADVERTISING

Sponsor.—United Prune Growers of California, a marketing organization for 85 per cent of the prune growers of California.

Description.—United Prune Growers of California educational advertising for California grown prunes

Handling and Processing.—Mature prune plums dropping from the tree by their own weight are conveyed to a central drying plant, immersed in boiling water or alkali solution (1 pound of sodium hydroxide to 20 gallons of water) for fifteen seconds to crack the skin to facilitate drying. The alkali is removed by water sprays. The fruit is dried on wooden trays in the sun for from five to ten days or in dehydrators for twenty-four hours. About 30 per cent of the harvest is dried by the latter method. The partially dried prunes are allowed to "sweat" in bins to equalize their moisture content and are then sent to central packing houses, where they are cleaned by hot water sprays, passed slowly through nearly boiling water, shaken to remove adhering water, inspected by gloved workers, and automatically or semiautomatically packed in boxes and paper or cellophane cartons or bags, cooled and shipped. The fruit retains a temperature of over 63 C. for not less than five hours' after the heating.

Analysis (submitted).—

per cent

Pits (per cent of entire prune)	14.9
(Representative analysis of flesh of prunes from three main growing sections)	
Moisture	18.4
Total solids	81.6
Water soluble solids	78.0
Ash	2.2
Alkalinity of water soluble ash (cc. N-acid per 100 grams prune flesh)	20.5
Alkalinity of acid soluble ash (same)	7.3

Potassium (K)	0.91
Sodium (Na)	0.07
Sulphur (S)	0.02
Potential alkalinity (excess base forming elements in terms of cc. normal alkali per 100 grams prune flesh) ⁵	24

Calories.—3.1 per gram of flesh, 88 per ounce of flesh.

Vitamins.—500 Sherman units of vitamin A, 22 Sherman units of vitamin B and 80 Sherman units of vitamin G respectively per ounce

Claims of Sponsor.—California prunes are laxative, owing to bulk and certain natural extractives that stimulate intestinal activity. Among the outstanding fruits richest in iron. An excellent source of quickly available food energy owing to the high content of readily assimilable sugars. Recent biologic

tests show that the addition of 200 Gm. (eighteen prunes) per day to the usual diet has no effect on the alkali reserve of the body except to narrow normal variation.

IRRADIATED VITAMIN D PASTEURIZED
MILK

Distributors.—1. Carlson-Frink Company, Denver. 2. Stefan's Dairy Products, Oklahoma City, subsidiary of Southwest Utility Dairy Products Company. 3. Ira Wilson & Sons Dairy Company, Detroit.

Description.—Bottled pasteurized vitamin D milk irradiated with ultraviolet rays (patent No. 1,680,818).

Preparation.—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation see THE JOURNAL, Oct. 7, 1933, page 1155. Cherry-Burrell equipment is used.

Vitamins.—Clinical investigation shows this milk to be a reliable antirachitic agent if the proper amount is used. Contains 135 U. S. P. X (Revised, 1934) vitamin D units per quart.

Claims of Distributor.—Irradiated antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

FRANKFORD BRAND TOMATO JUICE

Distributor.—Frankford Grocery Company, Frankford, Pa.

Packer.—American Packing Corporation, Evansville, Ind.

Description.—Canned tomato juice with added salt; retains in high degree the natural vitamin content; the same as the accepted Triple AAA Brand Pure Tomato Juice (THE JOURNAL, July 2, 1932, p. 35).

"THE STORY OF SALMON" PROMOTIONAL
ADVERTISING

Sponsor.—Department of Home Economics, American Can Company, New York.

The purpose of the department is to distribute interesting and factual material on various canned foods.

Advertising.—The booklet "The Story of Salmon" discusses the natural history, conservation and canning of salmon as well as the nutritive value of canned salmon.

SILVER TIP BRAND PANCAKE TABLE SYRUP
SWEETHEART PANCAKE TABLE SYRUP

Manufacturer.—D. B. Scully Syrup Company, Chicago.

Description.—A table syrup; corn syrup flavored with refiners' syrup. The same as Banner Blue Corn Syrup with Cane Flavor (THE JOURNAL, March 5, 1932, p. 817).

MACY'S BABY FOODS

STRAINED APRICOTS

(ADDED SUGAR AND SULPHUR DIOXIDE)

STRAINED CARROTS, GREEN BEANS, PEAS,
SPINACH, TOMATOES AND VEGETABLE
TABLE SOUP

(SEASONED WITH SALT)

STRAINED PRUNES

Distributor.—R. H. Macy & Company, Inc., New York.

Packer.—Stokely Bros. & Company, Indianapolis.

Description.—Respectively strained apricots (added sugar and sulphur dioxide), carrots, green beans, peas, spinach, tomatoes and vegetable soup (all seasoned with salt), and prunes; prepared by methods efficient for retention in high degree of the natural mineral and vitamin values. The same as Stokely's for Baby: Specially Prepared Strained Vegetables and Fruits (THE JOURNAL, May 26, 1934, p. 1762; May 26, 1934, p. 1763; June 2, 1934, p. 1851; June 9, 1934, p. 1943; June 30, 1934, p. 2186; July 7, 1934, p. 29; July 14, 1934, p. 110; July 21, 1934, p. 189).

SATURDAY, NOVEMBER 10, 1934

COMMITTEE ON ECONOMIC SECURITY

Last June, as was pointed out in a previous editorial in *THE JOURNAL*,¹ President Roosevelt created a committee on economic security to look into plans and advise prospective legislation that will provide people with decent homes and productive work and "safeguard them against misfortunes which cannot be wholly eliminated in this man-made world of ours." The committee included the Secretaries of Labor, the Treasury and Agriculture, the Attorney-General and the Federal Emergency Relief Administrator. This committee established a staff and selected as secretary and executive director Edwin E. Witte, a labor economist long associated with the industrial commission of the state of Wisconsin. The committee set up a technical board of twenty persons in the government service with special knowledge of various phases of economic security and also established a staff of specialists to look into different aspects of the subject.

In a bulletin for the press, just issued, it is pointed out that there is contemplated an advisory council to be named by the President. This council is to be composed of representative citizens who will advise on broad general policies. A special medical advisory committee is also to be appointed. In its first bulletin the Committee on Economic Security said, "Following the approach outlined by the President, the Committee is trying to draw up a comprehensive program which will give protection to the individual from all the vicissitudes and hazards of modern life—unemployment, accident, sickness, invalidity, old age, and premature death." The report of the committee is due to be made to the President on December 1 and will not be made public until released by the President.

Following the publication of the editorial that appeared in *THE JOURNAL*, a statement was received from Miss Perkins to the effect that a group of distinguished physicians would be constituted as an advisory board in the field of medicine. In a recent statement Miss Perkins announces that the medical

advisory committee will consist of eleven eminent physicians and surgeons from all parts of the country, including the presidents of the three principal national organizations. Other advisory committees are to be created in dentistry, hospital management and public health. Pursuant to the receipt of the letter from Miss Perkins, the chairman of the Board of Trustees of the American Medical Association offered to the Committee on Economic Security the information assembled by the Bureau of Medical Economics of the American Medical Association. In the bulletin just issued by the committee it is pointed out that the Committee on Economic Security plans to consult with Dr. R. G. Leland, director of the Bureau of Medical Economics of the Association, and that it welcomes constructive suggestions from any one for meeting the economic problems arising from illness in families with low incomes.

Edgar Sydenstricker, chief statistician of the United States Public Health Service and director of public health activities for the Milbank Memorial Fund, has been placed in charge of the studies which it is hoped will yield "the best possible means for providing adequate medical care for those who are without means." It will be remembered that Mr. Sydenstricker as a member of the Committee on the Costs of Medical Care brought in an independent minority report in which he pointed out that the recommendations of the majority and the minority did not, in his opinion, go far enough. It will be remembered also that at the meeting of the American Academy of Political and Social Science, held in Philadelphia last February, Mr. Sydenstricker presented the following pragmatic approach to the problem:

There is, of course, no one solution. It seems to me that the needs of the situation must be met by a combination of methods. Those who compose our well-to-do class can continue to purchase the medical care to which they are accustomed and the physicians who serve them can reap the benefits of an economic system which permits the concentration of purchasing power within that class. I am not here to argue for or against the existence of such a class; that question is outside of the bounds of our discussion. We accept the fact, so far as medical care is concerned, as a condition. Those who are too poor to pay for medical care must be given medical care; the only change in the present situation would be the payment, on an adequate basis, of physicians and others for rendering good medical care to this unfortunate class. For the most expensive services—the treatment of those afflicted with mental diseases, tuberculosis, cancer, orthopedic defects, the impairments resulting from poliomyelitis and the like—the public must assume an increasing responsibility. But the great majority of people—those who earn their livelihood in the American way of living, who want to pay for their medical care—are not in a position to budget the unpredictable costs of medical care. In almost every other unpredictable contingency the method of insurance has been applied with success in our own country. In almost every other country this method of distributing costs has been applied in a partial way to sickness. We should go beyond the health insurance systems of Great Britain and Europe which provide medical care to employed individuals only, and we should go further than to provide public medical service for infants, children, and mothers, or for tuberculosis and mental diseases. All kinds of medical care, at home or in institutions, should be provided;

1. The Administration Studies Social Insurance, editorial, J. A. M. A. 103: 609 (Aug. 25) 1934.

and those who receive this care should include not merely those who are employed but all persons and their families having incomes below an amount sufficient to purchase medical services in any contingency. We should leave cash benefits during sickness to be taken care of by unemployment or by commercial insurance. No proprietary or profit-making agencies should be included and no independent intermediary between the potential patient and medical agencies should be permitted. In such a program the maintenance of the physician's professional freedom is of cardinal importance; adequate remuneration of all who render medical service is necessary, and the promotion of higher quality of medical care, the professional administration of professional personnel and activities, the maintenance of the private relationship between physician and patient, and the patient's free choice of physician are obviously essential.

We are informed that Dr. Walter Bierring, president of the American Medical Association, Dr. James Alexander Miller, president of the American College of Physicians, and Dr. Robert B. Greenough, president of the American College of Surgeons, have accepted positions on the medical advisory committee and that a conference of the various advisory bodies will be held in Washington on November 14 and 15. Dr. Olin West, secretary of the Association, has been asked to attend this conference. It should be borne in mind that the staff headed by Mr. Witte, the technical consultants and the advisory groups will eventually consummate their efforts in reports and plans which are to be turned over to the Committee on Economic Security and that this committee will then give to the President its suggestions as to how economic security is to be provided for those of our population who are said to require it. Presumably there will eventually be proposed legislation on which hearings will be held by Congress in the usual manner. Physicians should be aware of the various phases of this matter. The various bureaus and officers of the Association, including the Board of Trustees, are in intimate touch with the activities now under way and are doing their best to make certain that the point of view of organized medicine is adequately presented.

DISEASE AS A MENTAL STIMULUS

The relation of bodily disease to the character and nature of mental activity is always an interesting subject for study and speculation. The neuroses, the psychoneuroses, the hysterias and their connection with physical ills provide a ceaseless flow of professional literature. The long list of successful invalids suggests the possible mental stimulus of disease. Perhaps her physical frailty inspired Elizabeth Barrett Browning. Robert Louis Stevenson "suffered from infancy from great fragility of health"¹ and later developed tuberculosis. Sydenham, whose treatise on gout is such a masterpiece, wrote it probably because he had it himself. In such instances one may postulate the physical condition as a mental stimulant. The effect of the development of dementia paralytica on the writing of

de Maupassant would in itself be an interesting study. When viewed statistically, however, it is questionable whether physical or mental illness is more frequent in men of genius than in the population at large. Thus Hart² has drawn up a list of 100 representative geniuses and found nine who, at one time or another, showed psychotic or psychopathic traits and thirty-three who suffered at some period of their lives with ill health. Such proportions probably would not differ materially from those of the general population at the times when these geniuses lived. Hunger also, as a bodily discomfort similar to disease, has been discussed as a possible mental stimulant.³ Reed cites Goldsmith as an example and states that, "among the litterateurs of the past, we find numerous instances, too numerous to be accidental, in which the work which brought renown was done during a period of hardship." Financial hardship other than absolute hunger can produce this urge, as witnessed by the prodigious literary activity of Scott under conditions of financial stress. On the other hand, Hart² found that practically half of his 100 men of genius were economically secure all their lives and 77 per cent either were always secure or attained security. Such economic comfort must be far above that of the people as a whole.

Departing from the individual, what has been the effect of disease on the course of civilization? Granting the probability that human mental capacity has not changed materially in the last thirty thousand years, what effect can disease have had in racial development? Has natural selection by disease eliminated the mentally unfit? This seems scarcely likely in view of the present statistics. Certainly disease, especially epidemics, has influenced the geographic distribution of many peoples and hence their history.⁴ The fact is certain, the exact manner uncertain. Some diseases have undermined the abilities of whole peoples, others have driven people to greater activity or to lands of better opportunity. The frequent decimations of population resulting from disease may have either delayed the advance of civilization or stimulated the remaining people to greater effort than had been necessary before.

This possible stimulating effect of disease on the collective growth of civilization has been the subject of a recent address.⁵ According to Pusey it is the need to surmount the difficulties of life that has been the spur that has urged man on to mental as well as physical effort. The elemental stimuli to progress are relatively few—hunger, sex, social propensity, vanity, injuries, disease, and danger from beasts and men and from the elements and natural hazards. Of these, few have more constantly prodded man in his progress than the injuries, pains and illnesses that have beset him.

4. Dempster, J. H.: Disease as a Factor Influencing History, *J. Michigan M. Soc.* 33: 146 (March) 1934.

5. Pusey, W. A.: Disease, Goad of the Mind, *Brit. J. Dermat. & Syph.* 46: 341 (Aug.-Sept.) 1934.

1. *Encyclopedia Britannica*: Robert Louis Stevenson.

Thus from Egypt and Babylonia to Greece, from Imhotep to Hippocrates, medicine is found to be one of the chief concerns of the mind. Pusey quotes Heide! as saying "It is not mere chance that Aristotle in this connection draws most of his illustrations from the field of medicine. . . . The extraordinary frequency of their [the Greeks'] appeals to medical practice in illustrations of scientific procedures . . . justifies the assumption that medicine along with mathematics afforded the best examples of science in the fifth and fourth centuries, B. C." Skin disease and dermatology, according to Pusey, can allocate to themselves much of this credit, for, from the beginning of history, they have constituted one of the major interests of medicine. The great epidemic of leprosy in Europe, which began about 500 A. D., reached its height in the Crusades and died out in the sixteenth century, and bubonic plague were the worst afflictions of that plague-ridden period. Leprosy had two useful effects on the growth of medicine during this time. It was responsible for the development of hospitals and nursing, and it placed a new emphasis on the objective study of disease. In the development of knowledge of histology, contagion, bacteriology, infection, immunity, allergy and metabolism, skin diseases have played a prominent part.

Are these considerations an idle speculation? The difficulties besetting the path of individual advance and comfort have always challenged the ingenuity of mankind. Disease and want still oppress vast numbers and there is no reason to believe that the challenge will not again be met successfully.

RESISTANCE OF THE THYROID TO STIMULATING SUBSTANCES

In a recent discussion of antihormones,¹ the possible relation of these substances to the clinical use of glandular products was considered. The demonstration by Collip and his co-workers that circulating antibodies may be produced by the injection of various gland stimulating principles indicated the necessity for great caution in the use of endocrine preparations in patients. A subsequent publication by Loeb² of Washington University emphasizes further the complexity of the problem. He points out that the development of resistance in the thyroid to various stimulating substances is dependent not alone on the production of antihormones in body fluids; factors apparently within the gland itself appear also to play a large part in this phenomenon. Following the injection of a thyroid stimulating preparation, the rate of mitotic proliferation of the cells in the thyroid of the guinea-pig increases to a maximum in a few days and then decreases, presumably before sufficient neutralizing substance can be present in the blood to account for this change.

Histologic changes in the thyroid similar to those produced by the thyroid stimulating factor of the pituitary, but less intense, may occur following partial thyroidectomy and administration of iodide. The time relationship of the changes in rates of cellular proliferation are also similar in the two cases. Loeb believes that it is improbable that this reaction could be due to the development of circulating antibodies against iodide. Further, it is a general principle in endocrinology that increase in concentration of the product of a gland tends to suppress further secretion of that substance by the gland. This is true of the thyroid also: administration of thyroid hormone depresses the activity of the organ. Thus it appears that development of a refractory state in the presence of stimulating substances may result from the composite action of a number of factors.

The St. Louis investigator suggests that the development of antihormones may result from the presence of protein in the pituitary extracts employed from which the active fraction of the molecule has not been separated. The antibodies produced would therefore act not against the hormone itself but against the foreign protein introduced with it. While this may well occur, this thesis does not account for the fact that, as observed by Collip and Anderson,³ a mixture of the thyroid stimulating factor and a neutralizing serum not only does not increase the metabolic rate of the animal into which it is injected but may actually decrease it. This seems to indicate that the serum actually inactivates some of the thyroid stimulating principle of the animal into which it is injected. Furthermore, Anderson and Collip⁴ have shown that the pituitary glands of animals which have become resistant to thyrotropic hormone following its prolonged injection are lacking in this factor. While, as Loeb suggests, there may be other plausible explanations of these phenomena, the problem will not be settled unless and until it is found possible to separate the active principle from specific proteins.

It is not yet known where the circulating antibodies to gland stimulating hormones are produced in the body. The antithyrotropic factor apparently is not produced in the pituitary, as Anderson and Collip have shown that it may be developed in the absence of this gland. It would be important to know whether the antihormone to the thyroid stimulating factor can be developed in a totally thyroidectomized animal. The cellular mechanism presented by Loeb appears to be the fundamental one; the production of neutralizing substances in the blood stream is probably a secondary factor much as this occurs in immunity to disease.

It is too early to speculate as to the ultimate significance of these observations. The work of Loeb and of Collip and their co-workers demonstrates further the

bewildering complexity of endocrine interrelationships. Increasing knowledge of this subject reveals more and more the hazard entailed in clinical application of recent contributions in this field.

Current Comment

HOSPITALIZATION OF THE MENTALLY ILL

Members of the House of Delegates and others have been solicited by Dr. John M. Grimes to purchase a book that he has printed purporting to contain the results of the study recently made by the Council on Medical Education and Hospitals of the hospitalization of the mentally ill in the United States. Such individual use of the Council's material is, of course, wholly unauthorized. A report prepared by Dr. Grimes when he was employed by the Association was not published because in the opinion of the Council and an advisory committee of psychiatrists and neurologists his conclusions were not supported by the evidence presented. Two partial reports that have already been published will be supplemented when further studies have been completed.

THE METRIC EQUIVALENT OF THE TEASPOON

Although efforts have been made to introduce the use of the accurate graduated medicine glass for the measurement of liquid medicines, most people seem to prefer to take medicine from the teaspoon. For a long time it has been recognized that the present equivalent of a teaspoon is not a universal standard of measurement. Originally the teaspoon was considered the equivalent of the fluidrachm, which is about 4 cc.; this has been generally accepted since the metric system became official. This is, Nitardy says, an incorrect equivalent even though it has been adopted by the United States Pharmacopeia. Attempts have been made several times to have adopted the more nearly correct equivalent of 5 cc. The need for a more accurate equivalent has been repeatedly shown. Wilbert¹ long ago found that the teaspoonful dose as measured with the same spoon by different people varied from 3 to 7 cc. The capacities of various teaspoons as measured by Army² ranged from 3.8 to 7.8 cc. More recently Adams³ showed that the teaspoons of four different makes delivered amounts varying from 4.22 to 7.39 cc. The average content of a teaspoon in Europe is recognized as 5 cc. by the pharmacopeias of several countries. The British pharmacopeia does not give any capacity for a teaspoon. Nitardy⁴ determined the capacity of a European teaspoon that was more than a hundred years old and found it to be 4.4 cc. Since the average teaspoon obviously holds more than 4 cc, an effort should again be made to have a more nearly correct metric equivalent for the average teaspoon recognized in the United States Pharmacopeia.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next two broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

November 15 The Health Audit
November 22 Eat, Drink and Be Merry.
November 29 Holiday No broadcast

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

November 13 Does Medicine Cost Too Much? Morris Fishbein, M.D.
November 20 The Doctor of Tomorrow, W. W. Bauer, M.D.
November 27 Dollars and Disease, Morris Fishbein, M.D.

THE ATLANTIC CITY SESSION

Twenty-First Annual Tournament of the American Medical Golfing Association

Dr. Walt P. Conaway, Atlantic City, has been chosen chairman of the committee on golf for the annual session of the American Medical Association in Atlantic City in June 1935. The American Medical Golfing Association will hold its twenty-first annual tournament at the Northfield Country Club Monday, June 10. Dr. John P. Loudon, Yakima, Wash., is the present champion of the association, having won the Will Walter Trophy at Cleveland last June, with a score of 152 for thirty-six holes against a field of 185 players.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

District Meeting.—Dr. Jasper T. Matthews, Heber Springs, was elected president of the Second District Medical Society in Batesville, October 10. Dr. Paul H. Jeffery, Bethesda, vice president, and Dr. Oscar J. T. Johnston, Batesville, secretary. Speakers at this session included Drs. Fergus O. Mahony, El Dorado, "Present-Day Trend in Medicine", Edward Clay Mitchell, Memphis, "Upper Respiratory Tract Infections in Children"; Joseph F. Shuffield, Little Rock, "Principles in Treating Some of the Common Fractures," and Herbert H. McAdams, Jonesboro, "Fibroid Tumors of the Uterus." The next meeting will be held in Batesville, April 8, 1935.

CALIFORNIA

Society News.—Speakers before the Alameda County Medical Association October 15, were members of the surgical staff of Alameda County Hospital, Oakland: Drs. Theodore C. Lawson, "Traumatic Surgery"; Frank H. Bowles, "Anomalies of the Breast," and Sumner Everingham, "Fascial Repair in Hernia."

Personal.—Dr. Henry O. Howitt, San Rafael, has been appointed health officer of Marin County to succeed the late Dr. John H. Kuser.—Dr. Nazareth J. Crisp has been named city health officer of Benicia, succeeding the late Dr. Philip B. Fry.—Following her resignation as medical adviser to women and director of women's physical education at Stanford University, Palo Alto, Dr. Bertha S. S. Dymont is engaged in private practice.

Obstetric Meeting.—The Pacific Coast Society of Obstetrics and Gynecology will meet at Del Monte, November 21-24.

under the presidency of Dr. Lyle G. McNeile, Los Angeles. The following program will be presented:

- Dr. Karl L. Schaupp, San Francisco, A Study of Prenatal Care from Two Five Year Periods at San Francisco Hospital.
- Dr. Albert L. Mathieu, Portland, The Early Diagnosis of Chorio-Epithelioma.
- Dr. Albert V. Pettit, San Francisco, Repair of Pelvic Floor.
- Dr. Clarence A. DePuy, Oakland, Subarachnoid Injection of Alcohol for the Relief of Pain.
- Dr. John A. Sperry, San Francisco, Uterine Fistulas.
- Dr. Henry A. Stephenson, San Francisco, Critical Analysis of Maternal Mortality in San Francisco Hospitals.
- Dr. Thomas F. Wier, San Diego, Pituitrin and Narcosis in Labor.
- Dr. Frank C. Ainley, Los Angeles, Vomiting in Pregnancy.
- Dr. Norman H. Williams, Los Angeles, The Use of X-Rays in Obstetrics.
- Dr. Emil J. Krahulik, Los Angeles, Rupture of the Membranes Before the Onset of Labor.

DISTRICT OF COLUMBIA

Army Lectures.—October 15 marked the opening of the monthly lectures to which the medical department of the U. S. Army invites the medical and dental professions of the district. Lieut. Col. Sidney L. Chappell discussed "Brain Tumors, with Especial Reference to Encephalography as a Diagnostic Procedure," and Major Ira F. Peak, "Treatment of Syphilis of the Central Nervous System." This series of lectures will continue until May.

University News.—Surg. Gen. Robert U. Patterson, U. S. Army, gave the Smith-Reed-Russell lecture for October at the George Washington University School of Medicine, on "The History of Yellow and Typhoid Fevers in the U. S. Army." The annual banquet of the society was held October 23, and addresses were given by Dr. Charles Wardell Stiles of the U. S. Public Health Service and Henry B. Ward, LL.D., permanent secretary, American Association for the Advancement of Science, on "History of Hookworm Disease in the New World" and "Salmon Psychology," respectively.

GEORGIA

Society News.—Speakers before the Seventh District Medical Society at Coosa Country Club near Rome, September 26, included Drs. Evan O. Shellhorse, Dalton, on "Treatment of Infantile Diarrhea with Raw Apples," and James S. McLester, Birmingham, Ala., President-Elect of the American Medical Association, "Problems Relating to Vitamin Deficiency."—Among others, Dr. Tom V. Willis, Brunswick, addressed the Eighth District Medical Society at Waycross, October 9, on chronic malaria.—Drs. James L. Campbell and James E. Paulin, both of Atlanta, presented papers before the joint meeting of the Ninth District Medical Society and the Hall County Medical Society, September 19, on cancer and rheumatoid arthritis, respectively.

ILLINOIS

Personal.—Dr. and Mrs. Henry J. Heusinkveld, Fulton, observed their fiftieth wedding anniversary, October 1.—Dr. James J. Walsh, Camp Custer, Mich., has been named head of the medical department of the Veterans' Administration Facility at Danville, succeeding Dr. Aldine E. Morgan, who is being transferred to Oregon.

Chicago

Grant for Biologic Research.—The Rockefeller Foundation has made a grant of \$50,000 to the University of Chicago to carry on biologic research. This is an increase over the annual grant of \$30,000 which the foundation has given to the university for the last five years. The additional \$20,000 will be used to cover the expenses of the sex research program, which until this year has been financed by the committee on research in problems of sex of the National Research Council.

Dr. De Lee Awarded Medal.—Dr. Joseph B. De Lee, founder of the Chicago Lying-In Hospital, was presented with the Jesse L. Rosenberger Medal by the University of Chicago, October 28, in "recognition of his great service to humanity and of his lifetime of untiring devotion to his profession and his widespread influence on the practice and teaching of obstetrics." The presentation was made during a celebration given by the hospital board and the Mothers' Aid Club, observing the thirtieth anniversary of the latter and the sixty-fifth birthday of Dr. De Lee. A graduate of Northwestern University School of Medicine, 1891, Dr. De Lee is professor of obstetrics and gynecology at the Division of Biological Sciences, University of Chicago. In 1895 he founded the Chicago Lying-In Hospital, which, since 1927, has been affiliated with the University of Chicago.

Formally dedicated in 1931, the building cost \$1,900,000 and has a capacity of 157 beds.

Society News.—Dr. Achille Mario Dogliotti, professor of surgery, Royal University of Turin, Italy, addressed the Italian Academy of Medicine of Chicago and the staff of the American Hospital, October 22, on "Ventriculography" and "Treatment of Facial Spasm."—At a meeting of the Chicago Surgical Society, November 2, speakers included Drs. William F. Riehoff Jr., Baltimore, on "Total and Partial Pneumonectomy," and Fremont Chandler and Eric Oldberg, "Extrapyramidal Tract Section for Congenital Spasticity with Athetosis."—The Chicago Laryngological and Otological Society was addressed, November 5, by Drs. Andrew C. Ivy on "Physiology of the Labyrinth"; Sherman L. Shapiro, "Pseudocerebellar Abscess," and Francis L. Lederer, "Hemorrhage in Lung Cancer."—Speakers before the Institute of Traumatic Surgery, November 19, will be Drs. Edson B. Fowler, Evanston, Ill., and Harry R. Hoffman on "A New Operation for Habitual Dislocation of the Shoulder" and "Traumatic Neuroses," respectively.—Carlos I. Reed, Ph.D., assistant professor of physiology, University of Illinois College of Medicine, addressed the Chicago Club for the Study of Arthritis, November 7, on "Metabolic Changes in Arthritis Patients Under Viosterol Therapy."

INDIANA

Medical Museum.—Efforts are being made to establish a medical museum at Indiana University School of Medicine. Any one with old medical books, instruments or anything of interest to the medical profession who wishes to donate them to the museum should communicate with the bureau of publicity of the Indiana State Medical Association, 1021 Hume-Mansur Building, Indianapolis.

Personal.—Dr. Walter B. Christophel was recently elected president of the Mishawaka Chamber of Commerce.—Dr. Herman O. Seipel, formerly coroner of Porter County, has succeeded the late Dr. Harvey S. Cook as health officer of Valparaiso.—Dr. Junius L. Lamberi, Brazil, has been appointed health officer of Clay County, succeeding the late Dr. William Palm.

Survey of Handicapped Children.—The Indiana University psychologic center of Riley Hospital, Indianapolis, will sponsor a survey in the public schools of children with physical handicaps that retard their progress. Results of the investigation will be used to map out a program of training teachers to meet the problem presented by these children, the journal of the state medical association reports. Teachers will be asked to report students who stutter, lisp or have cleft palate, delayed speech, or sensory defects such as vision and hearing.

Society News.—A joint meeting of the Grant County medical and dental societies, Marion, October 23, was addressed by Dr. Joseph E. Schaefer, Chicago, on "Mouth Infections and Mouth Lesions."—At a meeting of the Madison County Medical Society in Anderson, October 15, Dr. Lawrence H. Gilman, Indianapolis, discussed encephalitis.—The Elkhart County Medical Association was addressed in Elkhart, October 4, by Drs. Nelson M. Percy and David S. Belin, Chicago, on "Gastric and Duodenal Ulcer and Carcinoma of the Stomach from Clinical, Roentgenologic and Surgical Viewpoints."—Dr. Jewett V. Reed, Indianapolis, discussed head injuries before the Gibson County Medical Society in Princeton, October 8.—Dr. Eugene Birchwood, Chicago, is giving a series of ten lectures on the interpretation of the electrocardiogram before the staff of Holy Family Hospital, LaPorte.—A symposium on rheumatic fever was presented before the Indianapolis Medical Society, October 25, by Drs. Russell R. Hippensteel, George S. Bond and Harold C. Thornton.

KANSAS

Society News.—Papers were presented by Drs. John L. Lattimore and Earle G. Brown, Topeka, before a meeting of the Clay and Geary County medical societies at Junction City, September 12, on fever determination and coronary thrombosis, respectively.—At a meeting of the Harvey County Medical Society in Newton, September 3, Drs. Harold M. Glover, Newton, read a paper on "Anemias of Pregnancy" and Emmet E. Peterson, Halstead, on "The Motor Paralysis of the Larynx."—Speakers before the Southeast Kansas Medical Society in Chanute, September 13, were Drs. Clifford C. Nesselrode, Kansas City, on cancer; Howard Snyder, Winfield, spinal anesthesia; William M. Mills, Topeka, treatment of lung abscess; Warren F. Bernstorff, Pratt, treatment of tetanus; Victor E. Chesky, Halstead, the goiter heart, and Noble E. Melencamp, Dodge City, use of iodine in thyroid disease.

LOUISIANA

Shreveport Fall Clinic.—The Shreveport Fall Clinic was held at Charity Hospital, November 8-9. Dr Willis C Campbell, Memphis, opened the session with an orthopedic clinic. Others on the program included Drs John R Caulk, St Louis, who discussed prostatic surgery, and fate of the kidney in cancer of the bladder, James S McLester, Birmingham, Ala., President-Elect, American Medical Association, newer aspects of deficiency diseases, James R McCord, Atlanta, Ga., puerperal eclampsia and puerperal sepsis, John H Musser, New Orleans, blood dyscrasias and observations on coronary occlusion, William D. Haggard, Nashville, Tenn., thyroid cases and cancer of the rectum, and Horton R Casparis, Nashville, nutrition in infants and children and childhood tuberculosis. Dr Campbell also discussed bone tumors.

Warning to Bakers.—The Louisiana State Board of Health has learned that some bakers consign bread and other products to retail dealers in quantities considerably in excess of their daily sales and requirements. Investigation shows that the left over products, which are picked up the following day and returned to the bakeries, are usually stored overnight in corners or store rooms where they are subject to contamination by roaches, rats, cats and the like, consequently they become stale and unfit for use as food. In many instances an attempt is made to freshen these returned products. The state board, as a warning, points out that the return of bread and other bakery products under these conditions would constitute a violation of the state food and drug law and regulations that make it unlawful for any one to trade in or exchange products unfit for use as food. The board urges bakers to adjust their deliveries to the actual daily requirements of their retail customers in the interest of public health and to protect their dealers and distributors from being charged under the food and drug law.

MASSACHUSETTS

Mental Hygiene Meeting.—The annual meeting of the Massachusetts Society for Mental Hygiene will be held at the Twentieth Century Club, Boston, November 22. Speakers will include Robert Ulrich, Dr Phil, lecturer on comparative education at the Harvard Graduate School of Education, whose subject will be "The Influence of the New Psychology on Education."

The Gay Lecture on Ethics.—Dr Arthur H Ruggles, Providence, R I, delivered the George W Gay Lecture on medical ethics at Harvard Medical School, November 1. The subject of his talk was "Understanding the Individual Patient." Lectures on the care of the patient will be given November 15 and 22 by Drs. Joseph H. Pratt and Stephen Rushmore, both of Boston.

State Hospital Opens New Unit.—A new medical and surgical building has been opened at the Metropolitan State Hospital in Waltham. In the future, patients with mental disorders who may require either medical or surgical treatments will be transferred to the new building. The unit, which is three stories high, has fifty-four beds for men and the same number for women. In addition, twenty-two beds are available for employees.

MICHIGAN

Personal.—October 11 was designated as "Dr Hudson Day" in Merrill, in honor of Dr James H Hudson, who has practiced in the community for forty-four years. A banquet was held at the Rainbow Hotel and he was presented with an armchair on behalf of the community. Dr Hudson, who is 76 years of age, graduated from the University of Michigan School of Medicine in 1883. He served as postmaster of Merrill for sixteen years.

Tuberculosis Meeting.—The Michigan Tuberculosis Society, the Michigan Trudeau Society and the Michigan Sanatorium Society convened in annual session in Ann Arbor, October 11. Speakers included Drs Jabez H Elliott of the University of Toronto Faculty of Medicine on "Tuberculosis in Children." Other physicians on the program included Drs Bruce H Douglas, Detroit, George L Leshe, Howell, Russell S Anderson, Howell, Warren E Forsythe and John Alexander, Ann Arbor.

Society News.—The program of the Kalamazoo Academy of Medicine was given in conjunction with the graduate course of the Michigan State Medical Society, October 16, speakers were Drs Carl D. Camp, Ann Arbor, "Technic and Methods of Neurologic Examination", Robert Dieterle, Ann Arbor, "Psychotherapy in General Medical Practice," and Isaac N. La Victoire, Kalamazoo, "Malarial Treatment of Syphilis of the Central Nervous System." Dr John M Dorsey, Ann Arbor, conducted a neurologic clinic.—Dr Robert Sonnen-

schein, Chicago, addressed the Saginaw County Medical Society at Saginaw, September 25, on "Practical Points in Otolaryngology for the General Practitioner."—Dr William J. Cassidy, Detroit, addressed the St Clair County Medical Society, October 2, on "Eccentricities of Splenic Disease: Treatment and Diagnosis."

NEBRASKA

District Meetings.—The Seventh Councilor District Medical Society held its annual meeting at Geneva, October 18, with the following speakers, among others: Drs Miles J Breuer, Lincoln, on "The Nature and Treatment of Infectious Arthritis," John M Porter, Concordia, Kan., "Use of Blood Transfusion in General Practice," and Joseph A Wernberg, Omaha, "Surgery of Acute and Chronic Empyema." Dr Joseph Bibb, Geneva, president of the state medical association also made an address.—At the annual joint meeting of the ninth and tenth councilor districts of the Nebraska State Medical Association in Kearney, October 9, speakers included Drs Wilmer D McGrath, Grand Island, on symptoms of angina pectoris, Charles F Moon, Omaha, practical obstetrics, and J Stanley Welch, Lincoln, estimating the surgical risk in thyroid cases.

NEW JERSEY

Health at Trenton.—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended October 27, indicate that the highest mortality rate (193) appears for Trenton, and the rate for the group of cities as a whole was 10.6. The mortality rate for Trenton for the corresponding period last year was 17.6, and for the group of cities, 10.5. The annual rate for eighty-six cities for the forty-three weeks of 1934 was 11.3 as against a rate of 10.8 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

NEW YORK

Medal for Work in Ophthalmology.—The University of Buffalo will award its annual gold medal to the author of a work on an ophthalmologic subject. Details may be obtained by writing Dr Harold W Cowper, 543 Franklin Street, Buffalo.

New York City

Second Harvey Lecture.—William Cumming Rose, Ph D, professor of biochemistry, University of Illinois, Urbana, will deliver the second lecture before the Harvey Society, November 15, at the New York Academy of Medicine. His subject will be "The Significance of the Amino Acids in Nutrition."

Pediatric Meeting.—A regional conference of the American Academy of Pediatrics with the New England Pediatric Society, the Philadelphia Pediatric Society and the pediatric section of the New York Academy of Medicine was held at the Ambassador Hotel, October 19-20. Among the speakers were

Dr John A Kolmer, Philadelphia, Vaccination in Anterior Polio myelitis
Dr William E Studdiford Jr, Birth Trauma
Dr Samuel T Orton, The Acquisition of Language
Dr Elvira Goettsch, Treatment of Scurvy, with Ascorbic Acid
Dr Joseph F McCarthy, Urology in Pediatrics
Dr Lucy D Porter Sutton, Persistent Auricular Fibrillation
Dr Marshall C Pease Jr, Hereditary Hemophilia Treated with Thelina
Dr Charles Hendee Smith, Lipoid Pneumonia

Voluntary Hospitals Give Forty Per Cent Free Care.—More than 40 per cent of the service rendered in 1933 by the fifty-six voluntary hospitals that make up the United Hospital Fund was given free, according to the fund's annual report. The hospitals provided 4,016,420 days of hospital care, of which 1,586,977 were free ward care, in the outpatient departments 1,794,877 visits were free out of a total of 3,951,391. The total operating expenses of the hospitals amounted to \$24,996,050, toward which they received in income from patients \$15,940,920 and in "miscellaneous earnings" \$985,824, leaving the remainder to be made up from other sources. The average cost of caring for patients in inpatient departments for all hospitals was \$5.33, for service to outpatients, 94 cents per visit. The percentage of occupancy of the 16,206 beds in the fifty-six hospitals was 69.7. The average stay in hospital for all types of institutions was 13.9; 12.8 for general and 17.3 for special hospitals. A total of 7,712 physicians exclusive of courtesy staffs served the hospitals of the fund and there were 18,834 persons employed by them during 1933.

OHIO

First District Meeting.—The annual meeting of the First Councillor District of the Ohio State Medical Association will be held in Cincinnati, November 12, with Drs. James Ewing and Frank E. Adair, New York, as guests. The morning will be devoted to inspection of the cancer clinic of the Cincinnati General Hospital, with discussion of cases by the guests. In the afternoon a session will be held at the hospital with the following speakers: Drs. Robert Conard, Wilmington, "A Simple Measure of Thyroid Dysfunction"; Louis G. Herrman, Cincinnati, "Peripheral Vascular Disease"; Harold O. Lund, Middletown, "Pyelitis in Infancy and Childhood," and Harry M. E. Lowell, Hamilton, "Treatment of Thermal Burns." The district society will join the Cincinnati Academy of Medicine for an evening meeting at its headquarters, at which Dr. Ewing will speak on "Recent Advances in the Scope of Cancer," and Dr. Adair, "The Attitude of the Modern Surgeon Toward the Cancer Problem."

PENNSYLVANIA

Society News.—Dr. Russell L. Haden, Cleveland, addressed the Erie County Medical Society, Erie, October 9, on "Classification and Treatment of the Anemias."—Dr. Robert S. Dinsmore Jr., Cleveland, discussed goiter at a meeting of the Berks County Medical Society, October 9.—Dr. Francis F. Borzell, Philadelphia, addressed the Schuylkill County Medical Society, Pottsville, October 9, on "Dangers of Socialized Medicine."

Graduate Assembly in Harrisburg.—Six speakers will present the program of a graduate assembly sponsored by the Harrisburg Academy of Medicine at the Penn-Harris Hotel, November 20, as follows:

- Dr. Lewellys F. Barker, Baltimore, The Senile Patient; The Treatment of Pernicious Anemia.
- Dr. John M. T. Finney, Baltimore, Extra-Abdominal Conditions Simulating Intra-Abdominal Lesions.
- Dr. Roy W. Scott, Cleveland, The Heart After Forty.
- Dr. Jacob Arnold Bergen, Rochester, Minn., Colitis, Its Pathologic Physiology and Management.
- Dr. John F. Erdmann, New York, Tumors of the Colon.
- Dr. John A. Kolmer, Philadelphia, The Etiology, Diagnosis and Treatment of Focal Infection.

Philadelphia

Ex-Residents' Dinner.—The forty-eighth annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held, December 4, at the Philadelphia Country Club. The guest of honor will be Dr. William A. Newman Dorland, Chicago. Ex-interns are urged to send their correct addresses to the secretary, Dr. George Wilson, 133 South Thirty-Sixth Street.

Tribute to Dr. Gleason.—Dr. Edward B. Gleason, professor of otology, University of Pennsylvania Graduate School of Medicine, celebrated his eightieth birthday, October 13. Dr. Gleason, a native of Philadelphia, is a graduate of the Medico-Chirurgical College of Philadelphia, where he was at one time professor of otology. He is the author of textbooks in otology and has served as president of the Philadelphia Laryngological Society. He was also at one time president of the Philadelphia Common Council.

County Society Seminars Begin.—Dr. Esmond R. Long delivered the first lecture in the first series of postgraduate seminars sponsored by the Philadelphia County Medical Society this season, November 2. The series is a study of tuberculosis, for which Dr. Long gave the historical background. Speakers for coming meetings will be:

- Dr. Morton McCutcheon, pathologic anatomy.
- Dr. Joseph D. Aronson, characteristics of the various types of tubercle bacillus and the tuberculin reaction.
- Dr. George A. Harrop, Baltimore, maintenance of nutrition in the tuberculous.
- Harvey Dee Brown, Ph.D., public health aspects.

Society News.—Dr. Leonard G. Rowntree addressed the Metabolic Association of Philadelphia, October 31, on diseases of metabolism.—Dr. Alfred Gordon addressed the Medico-Legal Society of Philadelphia, October 30, on "Some Basic Principles in Nervous and Mental Breakdown."—Dr. John F. Coppelino, among others, addressed the Obstetrical Society of Philadelphia, November 1, on "Prophylaxis of Congenital Syphilis."—At a meeting of the Philadelphia Roentgen Ray Society, November 1, Dr. Oscar V. Batson and LeRoy D. Ennis, D.D.S., among others, presented a paper on "Anatomical and Roentgenological Consideration of Maxillary Sinuses."

Pittsburgh

State Health Day.—The annual public health meeting under the auspices of the Allegheny County Medical Society and the General Health Council of Pittsburgh and Allegheny County in observance of Pennsylvania Health Day, was held

November 8 at the Hotel Schenley. Speakers were Drs. P. Starr Pelouze, Philadelphia, and William W. Bauer, Chicago, director of the Bureau of Health and Public Instruction of the American Medical Association.

SOUTH CAROLINA

District Meetings.—Among speakers who addressed the Fourth District Medical Association at Union, September 27, were Drs. William S. Fewell, Greenville, on "Heart Disease in General Practice"; Ruskin G. Anderson, Woodruff, "Bronchoscopy in Diagnosis and Treatment," and Francis P. Owings, Union, "Treatment of Cutaneous Burns."—At a meeting of the Seventh District Medical Association, Sumter, September 13, speakers on the scientific program were Drs. Addison G. Brenizer, Charlotte, N. C., on "Compression of the Spinal Cord—Its Surgery"; Robert W. McKay, Charlotte, "Urinary Obstruction in Male Infants"; Hal M. Davison, Atlanta, Ga., "Hypertension," and D. Lesesne Smith, Spartanburg, "Preventive Pediatrics." Drs. William Egleston, Hartsville, and Samuel E. Harmon, Columbia, president and president-elect, respectively, of the South Carolina Medical Association, discussed organizational and economic questions.—The Third District Medical Society held its annual meeting in Newberry, October 4, with the following speakers: Drs. James Heyward Gibbs, Columbia, on "Angina Pectoris"; LeGrand Gurry, Columbia, "Acute Abdomen"; Foster N. Martin Jr., Newberry, "Aplastic Anemia"; George Benet and Charles G. Spivey, Columbia, "Stab Wounds of the Heart." Dr. Samuel E. Harmon, Columbia, president-elect of the South Carolina Medical Association, made an address.

TEXAS

Meeting of Obstetricians and Gynecologists.—Dr. Henricus J. Stander, professor of gynecology and obstetrics, Cornell University Medical School, New York, was the guest speaker at the annual meeting of the Texas Association of Obstetricians and Gynecologists at Galveston, October 6. He delivered the J. F. P. Paine Lecture on "Maternal and Fetal Mortality in the United States" and addressed a dinner session on "Teaching of Obstetrics in the United States." Dr. Ben Hill Passmore, San Antonio, was elected president.

District Meetings.—The Fourth District Medical Society met in Ballinger, October 15-16, with the following speakers, among others: Drs. Stirling E. Russ, San Antonio, on "Treatment of Hemorrhoids"; Arthur G. Schoch, Dallas, "Recent Advances in the Treatment of Syphilis"; Charles P. Schenck, Fort Worth, "Traumatic and Unripe Cataracts," and Homer B. Allen, Brownwood, "Skin Grafting."—Among speakers at a meeting of the Northwest Texas (Thirteenth) District Medical Society at Bowie, September 11, speakers included Drs. Milton H. Glover, Wichita Falls, on "Chronic Arthritis of the Spine"; Louie O. Godley, Fort Worth, "Acute Anterior Poliomyelitis"; St. Julien R. Murchison and Craig W. Munter, Fort Worth, "Adequate After-Care in Prostatectomy and Transurethral Procedures," and John W. Brown, state health officer, Austin, "Relation of the Health Department to the Medical Profession and the Duties of Each."

WASHINGTON

Society News.—Drs. Albert C. Broders, Rochester, Minn., and William C. Speidel, Seattle, addressed the King County Medical Society, Seattle, November 5, on the cancer problem and on the development and present status of the transfusion of blood. Dr. William S. Middleton, Madison, Wis., addressed the society, October 15, on recent trends in medicine. Dr. Alexander H. Peacock, Seattle, showed motion pictures of a recent trip around the world.

Survey of Mental Health Facilities.—In accordance with a request of Governor Martin, the U. S. Public Health Service has detailed Senior Surgeon Grover A. Kempf, Washington, D. C., to make a study of mental health administration in the state. He will make detailed studies of institutions for the care of mental cases, including methods and policies of admission; of the penal and correctional system of the state, including court procedure, special clinics and provisions for temporary care and examination facilities pending trial, and of institutions dealing with delinquent and defective children, with special reference to mental hygiene problems. In addition, general studies will be made of population data, governmental organization, economic resources and fiscal policies and public and private educational policies. The scope of the survey also includes an analysis of policies affecting selection, training, appointment and tenure of office of those engaged in the care

and treatment of the mentally disordered. In the course of the investigation an analysis of the facilities and potentialities for research in nervous and mental diseases will be made.

GENERAL

Society News.—Dr. William Seaman Bainbridge was elected president of the Association of Military Surgeons of the United States at the annual session at Carlisle Barracks, Pa., October 10. The program consisted principally of demonstrations of medical field equipment and maneuvers. Assistant Secretary of War Harry H. Woodring made an address. The association visited the battlefield at Gettysburg, where the latest model airplane ambulance was exhibited.—Dr. Max Biesenthal, Chicago, was elected president of the Mississippi Valley Conference on Tuberculosis at the annual session in Cedar Rapids, Iowa, September 28. Mr. Theodore J. Werle, Lansing, Mich., was named vice president and Mr. A. W. Jones, St. Louis, reelected secretary. Dr. Merlin H. Draper, Fort Wayne, was elected president of the Mississippi Valley Sanatorium Association. The joint convention of the two organizations will be held in Madison, Wis., in September 1935.—National Hearing Week was observed during the week of October 15 by organizations for the hard of hearing, with addresses before various societies, radio programs and exhibits emphasizing the importance of the conservation of hearing.—Dr. Donald C. Balfour, Rochester, Minn., was chosen president-elect of the American College of Surgeons at the annual session in Boston, October 18, and Dr. Robert B. Greenough, Boston, was installed as president. Vice presidents elected were Drs. Arthur W. Allen, Boston, and John A. Gunn, Winnipeg, Canada.

Annual Meeting in El Paso.—The twenty-first annual meeting and clinical conference of the Medical and Surgical Association of the Southwest will be held in El Paso, Texas, November 22-24. Guest speakers will be:

Dr. Rosco G. Leland, Chicago, director, Bureau of Medical Economics, American Medical Association, Current Problems in Medical Economics.

Dr. Holman Taylor, Fort Worth, Special Phases of Medical Economics.

Dr. John H. Musser, New Orleans, Borderline Medical and Surgical Conditions.

Dr. John R. Caulk, St. Louis, Transurethral Surgery.

Dr. George Pines, Los Angeles, Problems in Diagnosis of Gastro-Intestinal Allergy.

Dr. John E. Pemberton, Rochester, Minn., Advances in the Diagnosis and Treatment of the Thyroid Gland.

Dr. Dudley A. Smith, San Francisco, Cancer of the Rectum and Rectosigmoid.

Dr. Harry L. Baum, Denver, Laryngotracheobronchitis.

The guests will also conduct clinics and round table discussions. Headquarters will be at the Hotel Hussman.

Society for Tropical Medicine.—The annual meeting of the American Society of Tropical Medicine will be held in San Antonio, Texas, November 14-16, in conjunction with the meeting of the Southern Medical Association. Papers on amebiasis will be presented by the following speakers, among others: Dr. Henry E. Meleney and William W. Frye, Ph.D., Nashville, Tenn.; Dr. Francis W. O'Connor and Constance R. Hulse, New York; Dr. George W. McCoy, U. S. Public Health Service, Washington, D. C.; Dr. Herman N. Bundesen, Chicago, and Charles A. Kofoed, D.Sc., Berkeley, Calif. Other speakers announced include:

Drs. Max Theiler and Loring Whitman, New York, Quantitative Studies of the Virus and Immune Serum Used in Vaccination Against Yellow Fever.

Dr. Thomas B. Magath, Rochester, Minn., Coccidia in Man.

Dr. Herbert C. Clark and William H. W. Komp, Panama, Further Studies of Malaria in Panama, with Reference in Control with Atabrine and Plasmodium.

Dr. Arnaldo Giovannoli, Italian Institute of Public Health, Rome, Plasmodium Ovale Considered as a Medium as a Modification of Plasmodium Vivax.

Dr. Hugh W. Mason, U. S. Public Health Service, Kasauli, India, The Malaria Parasite in Relation to the Human Host.

Chauncey D. Leake, Ph.D., San Francisco, Principles of Chemotherapy in Relation to Tropical Medicine.

Record Low Death Rate in 1933.—The U. S. Bureau of the Census announces that in 1933 there were 1,342,073 deaths from all causes, representing a mortality rate of 10.7 per thousand of estimated population, the lowest since the collection of mortality statistics was begun in 1900. The admission of Texas to the death registration area last year enables the bureau to publish complete statistics for the entire population of continental United States for the first time. Of eighteen groups into which the deaths are divided, eleven show decreases in rates as compared with the previous year, five show virtually no change, and only one shows a significant increase. The death rate from diseases of the circulatory system increased from 246 per hundred thousand of population in 1932 to 249.8 for 1933. The particular disease that showed the greatest

increase was diseases of the coronary arteries, which went from 14.5 in 1932 to 21.9 in 1933. The rate for 1932 was 10.8. The death rate from cancer, which has increased steadily during the past fifteen years, was temporarily halted in 1933, being 107, as compared with 107.1 for 1932. The rate for 1931 was 103.9. The group of infectious and parasitic diseases showed a decrease, chiefly attributed to a drop in the number of deaths from influenza and tuberculosis; diseases of the respiratory system had a lower death rate accounted for by a decrease in deaths from pneumonia, and diseases of the genito-urinary system revealed a decline in the number of deaths from chronic nephritis. Deaths from diseases of pregnancy, childbirth and the puerperal state also declined from 11.1 to 10.3 per hundred thousand of population in 1933. The suicide rate decreased from 17.4 in 1932 to 15.9 in 1933.

Deaths in Other Countries

Santiago Ramon y Cajal, for many years professor of normal and pathologic histology at the University of Madrid; winner of the Nobel Prize in medicine in 1906 for his work on anatomy of the nervous system; honorary president of the National Academy of Medicine of Madrid; director of the laboratory for biologic investigations in the Instituto Cajal, established in his honor in 1920; honorary member of scientific bodies in many countries, including the National Academy of Sciences in the United States and the Royal Society of England; honored by many prizes and medals from scientific societies and governments; author of textbooks in histology and anatomy; died, October 18, aged 83.—**Sir Richard Havelock Charles**, for many years physician to King George and Queen Mary of England; formerly professor of anatomy and comparative anatomy at Lahore Medical College; president of the Royal Society of Tropical Medicine and Hygiene and dean of the London School of Tropical Medicine; died in London, October 28, aged 76.

Government Services

Federal Fund for Rural Health

Health departments in rural areas will be subsidized by the U. S. Public Health Service through a fund of \$1,000,000 made available by the F. E. R. A. The funds will be disbursed through the state health departments to maintain existing full time county or district health units when local funds are insufficient to provide for adequate health service. According to the *New York Times*, the service will undertake to establish new full time rural units when local funds are inadequate to meet the entire cost, but it will not contribute to any project in which less than 50 per cent of the cost is borne by state or local authorities.

Position for a Parasitologist

The U. S. Civil Service Commission announces an open competitive examination for the position of junior parasitologist for the Bureau of Animal Industry, Department of Agriculture. At present there is a vacancy with headquarters at Beltsville, Md., in which the department wishes to place a woman. Both men and women will be admitted to the examination, however. The duties are to conduct research in animal parasitology, and the salary will be \$2,000 a year, subject to the usual deductions. Applications must be on file with the commission at Washington before November 26. Full information may be obtained from the secretary of the civil service board at the postoffice or customhouse in any city that has a postoffice of the first or second class, or from the commission at Washington, D. C.

Internships in the Public Health Service

The U. S. Public Health Service announces that a number of internships will be available July 1, 1935, to medical students graduating in that year. There will be a number of first year internships, the salary of which is \$79 per month plus quarters, subsistence and laundry, and a smaller number of second year positions with a salary of \$93.25 per month plus quarters, subsistence and laundry. Applications should be addressed to the U. S. Public Health Service, Washington, D. C., and the applicant should state whether he is interested in a first or second year internship. To be eligible for the second year, students must have had one year's internship by July 1, 1935.

Report of National Health Service

In the preceding letter the annual report for 1933 on the public health by Sir George Newman, chief medical officer of the Ministry of Health, was reviewed. The main part of the report was dealt with; a section on national health insurance has been reserved for special notice. It constitutes the most reliable information on the subject. Sir George Newman points out that the insurance medical service is a branch of the public health service which is concerned with the prevention and treatment of disease as it affects the insured population. The physicians who provide the service by virtue of their opportunities for the early detection of disease in the individual form the first line of defense against communal disease. In most cases they are also the best instrument for prompt application to the individual of preventive measures. The medical service given to the insured population is vastly superior to service to the same class of people before the introduction of national health insurance and has been improved continuously since its inception.

THE EXTENT OF THE SERVICE

In 1933 the number of insured persons in England and Wales was 16,071,000, while the number of insurance physicians was 16,500. The total cost of medical benefit, exclusive of the cost of administration, was \$44,700,000, of which \$33,800,000 was expended on remuneration of physicians and \$10,900,000 on medicine and appliances.

THE SUPERVISION OF INSURANCE PRESCRIBING

Sir George Newman points out that neither the insured nor the physicians have any pecuniary interest in the cost of medicines, which is a direct charge on the insurance funds. Therefore some form of supervision must be directed to the prevention of unnecessary expenditures. Particulars of the cost of the prescriptions of every insurance practitioner are extracted at regular intervals, and if these appear to disclose extravagance he is visited by a medical officer of the regional medical staff for the purpose of discussing whether more economical methods could not be adopted without loss of efficiency. If further action is required, the minister of health may issue a warning letter to the physician or may refer the case to the panel committee. In 1933 this committee found that unnecessary cost had been incurred in only four cases, a diminished number, for in 1928 the figure was forty-five.

THE QUESTION OF UNNECESSARY PRESCRIBING

The important question remains whether the general average cost of medicines is not unduly high. For several years the cost per head of the insured population has been steadily rising. Part of this is undoubtedly due to the necessity for prescribing expensive forms of treatment, such as insulin and liver extract. The suggestion is frequently made that the insured people of England are confirmed medicine drinkers. On this point it is interesting to compare Scotland, where the physicians generally never adopted the English custom of dispensing medicine to their patients, and the latter have not been induced to consider a bottle of medicine a necessary corollary of a visit to the physician. In England, on the contrary, the physicians have for generations dispensed all medicines to the working classes. The result of this difference is that the cost of medicine for the insured in England exceeds that in Scotland by 50 per cent. Sir George Newman points out that no facts connected with the incidence of disease in the two countries account for this

wide difference and no one would suggest that the standard of treatment in Scotland is lower than in England. In view of the steady increase in the cost of insurance treatment he enjoins the insurance physician to satisfy himself that every prescription is required by the patient's condition. There is no evidence that the standard of health is better in areas where the habit of taking medicine is highly developed. He finally suggests that possibly in order to ensure that due regard is paid to his advice the insurance physician supplies a bottle of medicine against his better judgment. That there is a considerable waste of public money because so many of the insured like to take medicine, for which they do not have to pay, seems beyond question. The *Lancet* suggests as a solution that the insured should be made to pay a small sum toward the cost of medicine.

MEDICAL CERTIFICATES AND CLAIMS FOR SICKNESS BENEFITS

Sir George Newman points out that any scheme of insurance which entitles the insured to money benefits is subject to the risk of illegitimate claims. Certificates of incapacity are not the least difficult of the physician's duties. Therefore in 1920 there was instituted a body of independent medical referees to whom doubtful cases could be referred for a second opinion. This innovation was welcomed both by the physicians and by the benefit societies. These referees play a most important part in the administration of sickness benefit. If a physician appears to have shown lack of care in the issue of certificates of incapacity, he is visited by an officer of the staff for the purpose of discussing both individual cases and difficulties in certifying generally.

Defense Against Gas Attack on the Civilian Population

Mr. Davidson Pratt, general manager of the Association of British Chemical Manufacturers and a member of the technical committee of the disarmament conference, delivered before the Glasgow section of the Society of Chemical Industry an address entitled "The Chemist and National Defense." He said that, in spite of the Geneva protocol, defense against chemical warfare was urgent. A country with a well developed air service and a strong chemical industry had the means ready at hand for a rapidly improvised gas attack on the enemy. Gas had a devastating effect on the morale of people ignorant of its properties and uninstructed in methods of defense. A country that had not educated its public or prepared schemes of defense would be particularly vulnerable. The safest thing for the civilian population was to keep within doors as soon as an air raid warning was given. To make indoor protection as safe as possible there should be in every house, office or building a gas-proof room or rooms in which the occupants could remain until the all clear signal was given. The selection of the rooms, from the point of view both of high explosives and of gas, and the means of making them as gas proof as possible, were problems for the chemist. There would naturally be some provision of gas-proof shelters for people caught in the streets. The proposal for extensive underground shelters, proof against high explosives and gas, was feasible only to a limited extent for certain limited services, because of the enormous expense. But a limited number of such shelters could be provided by peacetime construction of underground garages, for which there was a need. Those engaged in essential services would require gas masks and also oilskin clothing to protect them against airplane spraying and contamination by liquid splashes. Whether the rest of the civilian population would need gas masks was a difficult problem. It would not be possible to supply the millions that would be wanted in an emergency, and so it might be desirable to provide some simple type that would be on sale in peacetime and could be readily made by the million in time of war.

Dilaudidomania, a New Drug Habit

At a recent meeting of the Hospital Medical Society, attention was directed to the habit forming danger of a much exploited opium derivative, dilaudid. The advantages of this new drug over diacetylmorphine and morphine as a sedative for cough or pain were claimed to be that the dose was only one third that of the other preparations and that there was no danger of the formation of a habit.

Dr. Sainton opposes both of these supposed advantages. He has found that dilaudid gives the same feeling of euphoria and that there is the same craving for larger and larger doses until a habit is formed, as in the case of morphine and diacetylmorphine. One should be as careful in prescribing this new drug as if one were dealing with the older preparations.

Tetanus Without Demonstrable Atrium of Infection

At the July 3 meeting of the Paris Pediatric Society, Drs. Weill-Halle and Klotz reported a case of tetanus with typical but rather mild symptoms in a 4 year old child. Careful search failed to find an atrium of infection in the skin, the visible mucous membranes or the alimentary tract. Recovery followed the administration of antitetanic serum.

In the discussion of this paper, Dr. Apert reported a similar case in an older child in which, however, the atrium was in the intestine. Dr. Schreiber added another in a 9 months old infant without a demonstrable atrium of infection, also cured by serotherapy.

The use of relatively large doses of chloral as an adjuvant to serotherapy was recommended in the treatment of infantile tetanus.

The Father of Modern Advertising

No modern writer has been able to excel Balzac in the portrayal of all types of individuals, such as one finds in his various novels. Although written nearly a century ago, his books seem as full of interest as if they were written today. A French journalist has recently resurrected one of Balzac's characters, a Dr. Veron, who failed as a practitioner and tried journalism. During a luncheon with some fellow newspapermen, Veron predicted that the day would come when publicity for a toilet water or drug would attract as much attention as the review of a new book in their day. The doctor found a formula for a cough drop and exploited his product in the journals to such an extent that he soon waxed rich and was able to abandon both his medical and his journalistic career. The writer who has resurrected Dr. Veron believes that Balzac, through this character, can be regarded as the father of modern publicity.

Has Eugenic Sterilization Any Value?

Every medical student in France and its colonies must present a thesis in order to fulfil the requirements for graduations. Szwarcz (Thèse de Paris, 1934) chose as the subject of his thesis "The Eugenic Sterilization of Abnormals." Some of the author's statements are of interest and will be quoted here:

The arguments thus far presented to defend both the necessity and the efficacy of eugenic sterilization are not based on proved scientific data.

One is unable to prognosticate, except in rare instances, that diseases will be inherited. Aside from certain unusual diseases or familial malformations, the mendelian laws of heredity encounter serious objections.

The data of probable inheritance are too general and subject to too many variations to have any but theoretical value.

The application of average statistics to hereditary prognosis and to eugenic sterilization in special cases is too uncertain. It

frequently leads to serious errors because there is always a possibility that the future generation will be healthy.

It is too soon for geneticists to assume the rôle of experts in the form of being able to predict accurately the heredity of human diseases. The conscientious physician cannot therefore accept the principle of eugenic sterilization with all its practical consequences.

Hereditary stigmas frequently disappear completely or at least appear in greatly attenuated form in children born of diseased parents.

Eugenic sterilization has thus far not greatly decreased the total number in succeeding or even in the present generation. Modern methods of treatment have greatly influenced the possibility of transmission of hereditary taints. Observations covering a period of centuries show that the majority of mental and nervous hereditary stigmas are the result of alcoholism, tuberculosis and syphilis; in other words, the result of faulty environment, which should be conquered by other curative agents than sterilization.

BERLIN

(From Our Regular Correspondent)

Sept. 17, 1934.

Health Insurance in 1933

The Federal Bureau of Statistics has just published a preliminary report on health insurance in 1933. The report gives the number of *krankenkassen*, the number of members, the amount of dues paid and the total performance of the society. Since 1914, the number of *krankenkassen* has steadily declined. In 1914 there were 9,944 *krankenkassen*; in 1928, 7,426; in 1930, 7,183; in 1932, 6,611; in 1933, 6,427, and, at the end of 1933, 6,327 *krankenkassen*.

The average number of members in 1931 was 20,616,000; in 1932, 18,712,000, and in 1933, 18,525,000. While this was the yearly average, the total membership at the end of 1933 was about 1,600,000 greater than at the beginning of the year. The number of obligatory members was reduced by 127,000, and the number of voluntary members by 60,000. There are, however, still 3,400,000 voluntary members, 2,300,000 of whom are members of local *krankenkassen*. The administration of the *krankenkassen* requires the services of 34,300 persons. There are about two administration officials to each thousand members. The number of panel physicians is about 32,000. The monthly or quarterly dues have been considerably reduced. By the end of 1929, nearly 2,000 *krankenkassen* with nearly 12,000,000 members exacted dues in excess of 6 per cent of the wages of members; by the end of 1933 there were only 246 *krankenkassen* with 1,740,000 members still requiring 6 per cent of wages earned. For the granting of performances that exceeded those provided for in the by-laws, certain additional dues were demanded. Only those *krankenkassen* whose dues did not exceed 5 per cent of the wages earned could grant additional performances. This provision prevented 1,458 *krankenkassen* with 8,200,000 members from granting such additional performances. Other *krankenkassen* made use of this feature and paid an increased weekly sick benefit to those members who had to provide for others besides themselves. Further additional performances were granted in the form of special grants for medicine and minor remedies prescribed for members of the family. Some *krankenkassen* assumed (partially or entirely) the costs of minor remedies, cordials and major remedies. Still others paid part of the hospital charges. In the matter of aid for puerperants, the legally prescribed amounts were exceeded by few *krankenkassen*. On the other hand, a number of *krankenkassen* granted an additional amount for a burial, the usual allowance being twenty times the fundamental wages. Nearly 40 per cent of all the *krankenkassen* paid twenty-five times the wage scale, or an increase of 25 per cent. About the same

portion of the *Krankenkassen* paid the burial allowance in the event of the death not only of the head of the family but also of other members of the family.

Further Details on the Sterilization Problem

Since the last report (*THE JOURNAL*, September 15, p. 849), a number of new facts have developed. The previous report contained accounts of the activities of the recently established eugenics courts. In the meantime, figures on the workings of the sterilization law in Baden have been published. Up to June 15, 1934, 3,025 petitions for sterilization had been filed, which represented about 1.2 per thousand of the population. Sterilization was legally ordered in 997 cases and refused in thirty-two cases. Up to the date mentioned, the intervention had been applied to 289 men and 283 women.

Some time ago, the execution of the law was lagging far behind, as the federal minister of the interior emphasized in an official statement. Especially urgent are the procedures against such persons as present the gravest danger of producing offspring with serious hereditary defects. A speeding up of the work of the eugenics courts is necessary for the reason that it is desirable to put an end to the overcrowding of the institutions for mental patients. A great part of the institutions, owing to the executive order that inmates who have hereditary diseases may not be dismissed until a petition pertaining to their individual case has been presented and a decision has been reached, are filled to capacity. The result is that there is danger that new patients seeking entrance cannot be admitted. Therefore, if need arises, several separate chambers in the individual eugenics courts should be organized.

In accordance with a suggestion of the Prussian minister of justice, in the detection of persons amenable to the law, special attention should be given first to the weakminded and schizoid psychopaths, and, secondly, to the criminally inclined juveniles who have been gathered in the penitentiaries, where there are doubtless large numbers of persons who should be sterilized. The decision will be made when such juveniles have reached the age of 20, at which time the list of penalties imposed is already fairly large.

In Saxony, a detection center for weakmindedness, insanity and epilepsy has been established. This detection center is designed for patients with respect to whom a well balanced decision as to whether they belong to the designated groups of hereditary patients could not be secured by putting them in an institution, or in any other way, and for whom therefore a precise psychiatric observation is needed to clarify their condition.

The federal bureau of health instituted a preliminary inquiry in twenty-one institutions for mental patients and epileptic and weakminded persons, concerning which Dr. Dornedden gave a report. It was found that for these 24,000 inmates, at the end of 1933, the duration of treatment, in the same institution, per hundred inmates, was as shown in table 1.

TABLE 1.—Duration of Hospital Stay of Various Groups

Age Groups	Percentages						
	Under 1 Year	1-3 Years	3-5 Years	5-10 Years	10-15 Years	15-20 Years	Above 20 Yrs.
Under age 20.....	19.7	24.7	22.5	26.1	6.4	0.5	...
20-29 age group.....	16.6	20.9	15.6	23.7	11.6	3.4	3.1
30-39 age group.....	13.2	16.0	13.1	25.9	16.2	6.0	9.6
Age group above 40.....	14.1	15.4	10.7	20.7	14.1	6.0	19.1
All groups.....	16.1	18.8	14.7	25.5	12.8	4.4	7.7

It appears from this table that on Dec. 31, 1933, about half of the inmates had been resident up to five years, 25 per cent from five to ten years, and 25 per cent more than ten years, in the same institution. Former stays in other institutions are

not considered, so that these figures are low. About three fourths of the inmates of institutions were from 20 to 59 years old, whereas, of the total population of the German reich, only 57.5 per cent belonged to these age groups. Likewise, the proportion of persons more than 60 years old is higher than the proportion of that age in the total population.

TABLE 2.—Sterilization in Its Bearing on the 24,215 Inmates of Institutions

Type of Disease	Percentage of Inmates Affected	Percentage Requiring Permanent Hospital Care	Percentage of Patients Presumably	
			Dismissible Later	Without Sterilization
Congenital weakmindedness.....	23.2	70.8	26.8	2.4
Schizophrenia.....	43.5	69.0	24.6	6.4
Manic-depressive insanity.....	2.5	39.8	28.0	32.2
Hereditary epilepsy.....	10.7	65.3	23.7	6.0
Hereditary chronic chorea.....	0.2	83.0	9.4	7.5
Other diseases.....	19.0	62.2	7.6	30.3
	100.0	67.0	22.5	10.5

It is evident, therefore, that about two thirds of the inmates of institutions are in need of constant care, while 22.5 per cent may possibly be subjected to sterilization and be allowed their liberty. That amounts, for a total of 160,000 inmates in all such institutions, to about 36,000 sterilizations, which does not take account of the patients admitted each year, of whom presumably less than two thirds need permanent care and hence more than 22.5 per cent may be regarded as possibly amenable to sterilization.

Aug. 31, 1934.

Meeting of Gastro-Enterologic Society

Members of the Società di gastro-enterologia met recently, for the first time, in Milan, at the Clinica Medica, under the chairmanship of Professor Zoia.

Allodi of Turin presented a paper on achylia gastrica. Theoretically the term "achylia gastrica" should be applied only to those cases in which various tests furnish evidence of a complete and persistent absence of the secretory function. Practically, however, it is logical to include those cases which, aside from a complete absence of acid, present a marked deficiency, with reference to certain other tests. The condition is more prevalent in women than in men. The pathogenesis, according to modern views, is connected with previous inflammatory gastric lesions. As to etiology, importance attaches to endogenous factors (micro-organisms and toxins) originating in the region of the portal vein and the liver. One may distinguish a true achylia from false achylia.

Fasiani and Chiatellino of Padua spoke on the anemias that sometimes follow gastric resection. Total gastrectomy appears to lead frequently to an anemia of the pernicious type. Gastric resection in general leads in a small number of cases to states of simple hypochromic anemia. The practical importance of these hypochromic anemias in connection with partial gastric resections is, from the surgical point of view, not great, because they are rare and easily controlled by treatment. If one chooses the method of resection, the first method of Billroth appears preferable, since, aside from other values, it has the advantage of rendering the disposition to anemia less frequent.

Vespignani and Lenarduzzi of Padua presented a paper on radiologic research in achylia gastrica. Radiology serves to exclude those conditions which may be confused with achylia, the recognition of some of which is aided by the radiologic examination. Radiology may also aid in the diagnosis of

achylia by pointing out the existence of cancer of the stomach or linitis plastica, which may be confused with achylia.

Many conventionists participated in the discussion. Professor Donati of Turin stated that, since achylia gastrica is not an independent entity, it did not seem correct to attempt to describe its symptomatology. In sixty persons operated on for gastric and duodenal ulcer, he had never observed signs of pernicious anemia or grave secondary anemias. Sisto holds that the gastric lesion is to be regarded as due to an impairment of the antianemic substance or influence existing in the stomach. Schiassi called attention to a peculiar syndrome that he had observed and that may be considered under three heads: anemia, hepatosplenomegaly and a type of underdevelopment that may be very marked. He said he was unable to point out the causal factors of this type, but from the point of view of practical medicine the diagnosis is now certain and the therapy is nearly always successful.

Factors That Act on the Pressure of the Cerebrospinal Fluid

Debeus reported to the Società medica of Gorizia the results of his study on the pressure of the cerebrospinal fluid. In cases of intracranial hypertension, as in cerebral tumors and in fractures of the cranium, intravenous injections of methenamine or from 30 to 50 per cent solutions of dextrose are to be recommended. Rachiocentesis gives only temporary aid.

In schizophrenic patients (145 cases observed) the cerebrospinal fluid frequently presented a slight increase of pressure, in addition to a small increase of the proteins and globulins.

Sussi recalled that hypertonic substances find a wide application in the treatment of persons with cranial traumas, in which there is ordinarily a state of hypertension. In the surgical department of which he is director more than 300 cases have been treated in this manner, without lumbar puncture ever being applied. The substances used were a 20 per cent solution of magnesium sulphate, a 40 per cent solution of dextrose, a 40 per cent solution of methenamine, and caffeine.

Antituberculosis Convention

In the Clinica Medica of Genoa the first Ligurian antituberculosis convention was recently held. The three schools that establish the trend in Italy of the modern crusade against tuberculosis are the immunizing school, represented by Professor Maragliano; the constitutional school of preventive medicine, of which Professor Pende is the head, and the school of the curative method of tuberculosis based on artificial pneumothorax.

Professor Pende, director of the Clinica Medica of Genoa, in his address described the purposes of the convention, which was based on the two most important problems of modern social phthisiology: the most suitable method of treating the first tuberculous lesions in young persons and the organization of sanatorial climatic treatment. During a period of six years in which Professor Pende examined 9,752 Ligurian children and workmen in the factories, he found that 2 per cent of the young persons apparently healthy present progressive tuberculous diseases of the lungs. In regard to sanatoriums, Professor Pende emphasized the need of erecting such institutions in the plains and in high plateau regions having an altitude of from 1,100 to 1,300 meters, for the application of mountain treatment, which he considers highly indicated.

Professor Morelli stated that an important feature of the crusade against tuberculosis is the study of the constitution of the victims, which will make it possible to treat rationally all those who are found predisposed to the disease. From more than 50,000 a year, the number of deaths from tuberculosis in Italy has declined to 35,000, as a result of the progress in prophylaxis in the schools and the offices, and of climatic therapy.

VIENNA

(From Our Regular Correspondent)

Sept. 24, 1934.

Organization of Blood Donors in Vienna

An important recent creation of the public health service concerns the organization and documentation of blood donors, who must be ready to furnish at any moment from 300 to 500 cc. of blood. At present there are about 300 professional blood donors in Vienna (mostly unemployed persons), who are kept under constant supervision. For the past eighteen months the following system has been followed: In the General Hospital a room has been equipped for the accommodation of twelve men, who constitute the "blood donors for the day." From six to ten donors are needed every day, and the addresses of twelve other donors who can be secured within a short time make provision for emergencies. Every donor carries on his person his "certificate," in which, along with his photograph, there is a record of his blood group and the results of his blood examinations, which must be repeated monthly, and in which every transfusion is recorded, which prevents any immoderate use of a donor. Women are not much in favor as professional blood donors, although it is planned to use more women than formerly. The use of women presents certain difficulties and will require some changes in the organization of the system. The usual fee for a transfusion of 500 cc. of blood is 80 shillings (about \$16), although higher fees may be charged if the donor is called to a private sanatorium. An attempt is made to take each blood donor in his turn, as far as possible, in order that all of them may be equally employed. Of the six women at present on the list (aged from 20 to 25 years) two are always available, and it is planned to admit others to the list, in order that the difficulties associated with menstruation may be overcome. The record for the number and amount of his transfusions is held by a young athlete who, within a period of eight years, has served thirty-six times as blood donor. He is only 25 years old, but he has already supplied about 18 liters of blood. On a certain occasion he served twice as a donor within three days, but that is no longer permitted. The donors state that the loss of half a liter of blood weakens them scarcely perceptibly—after two or three days they are completely restored. As for the indications for transfusion, that intervention is resorted to now in extensive burns, in poisonings, in operations with great loss of blood, in diabetes, in various forms of primary and secondary anemia, and—of late—in cancer patients.

Statistics of Vienna Physicians

Statistics collected by the board of health of Vienna show that 3,935 physicians were registered in 1933 as entitled to practice medicine. Of that number 1,110 were specialists, 650 were dentists and 730 were hospital physicians; 962 were permanently engaged as physicians to the *kranken-kassen*; in addition, 2,760 physicians were part-time assistants to the *kranken-kassen* but had no fixed appointment. All physicians treated members of the *kranken-kassen* occasionally and were paid for their services in the individual case. It appears that, aside from the hospital physicians, who are not permitted to engage in general practice, nearly all the physicians of Vienna derive their subsistence, at least in part, from the *kranken-kassen*. The total number of physicians is not much greater than last year. The number of specialists shows considerable increase: 1,110 as against 920 in 1932. The number of hospital physicians shows a decrease, having dropped from 800 to 720, as stated. Many hospital physicians have been dismissed without new appointments having been made. A classification of physicians according to their religious faith has been attempted. It is held that the number of Jews and of non-Jews is about equal, although the number of Jews in Vienna is something over 10 per cent. In addition to these practicing physicians,

there are in Vienna about 240 medical officials, who are not allowed to practice but serve as government or municipal physicians or as health officers.

Sale of a Medical Practice as an Ethical Problem

The economic crises have brought up the question as to whether a physician or his heirs are justified in endeavoring to realize on the capital represented by a medical practice. Many discussions on the subject have been held of late at sessions of the *Wirtschaftliche Organisation der Aerzte* of Vienna, and two opposite opinions have been defended. Whereas the lawyers expressed the view that developments of modern economic life have tended to cause the medical profession to be regarded as a commercial enterprise, which can be bought or sold the same as any other business undertaking, the members who cling to medical traditions held the view that a medical practice "rests primarily on ethical principles" and not on the acquisition of money as does a business. They are absolutely opposed to the idea that a medical practice, which nearly always is based only on purely personal qualities, shall be made the object of a commercial transaction. The confidential relation between the physician and his patient is not a marketable product and cannot be transferred to another person at will. Up to the present, too, the laws of Germany, Austria and Czechoslovakia have been opposed to all commercial transactions involving a medical practice. But, when a dental practice or medical institution, such as a sanatorium or hydro-electrotherapeutic institutions, are the interest involved, the law views the matter in the same light as any other enterprise constituting a source of revenue. It may be said, therefore, that the majority of the leaders of the medical profession are opposed to the transfer of a medical practice for a monetary consideration. It is generally recognized, however, that this is the standpoint of the older generation. The younger physicians take a more practical view of the matter, and, while they also are convinced of the need of upholding strictly the ethics of the profession, they do not regard the sale of a medical practice, by any means, as a misdemeanor or impropriety but rather as a dire necessity conditioned by the inexorable developments of modern life.

Cancer of the Gastro-Intestinal Tract

At a session of the physicians of the *Kärntener Spital*, Dr. Förster discussed recently the modern views on ulcers of the digestive tract. As yet none of the theories advanced in explanation of the causes of ulceration have found general acceptance. There is general agreement that ulcers are not due to a purely local process but are the result of a disturbance of the vegetative nervous system. There has been a marked increase of ulcer disease in recent decades. Statistics of various hospitals in Austria show that in 1898 only 0.07 per cent of the clients were "ulcer" patients (departments of surgery and internal medicine). By 1930 the percentage had risen to 5.7. This increase is due in part to the fact that formerly an ulcer often escaped diagnosis. With the coming of roentgen rays and the progress of modern surgery, physicians have learned how frequently ulcerations occur. But, aside from this fact, it is evident that there has been a steady increase of ulcer disease in civilized countries. Ulcers are therefore becoming a heavy burden on the department of public welfare. Ulcer disease should therefore receive the same attention as cancer, rheumatism and tuberculosis. In spite of progress in diagnosis and treatment, it is a cardinal demand that the fundamental cause of ulcer be discovered.

Prof. Dr. Max Sternberg

The death of Prof. Dr. Max Sternberg, an eminent internist, after a long illness, at the age of 71, has been announced. As a student his keen powers of observation and his knowledge of physiology attracted attention, so that he soon became an

assistant at the Physiologic Institute and at the Institute of Internal Medicine. In 1894 he was appointed instructor and in 1903 a professor. He published many articles on the heart, nervous disorders and industrial diseases, and was one of the first to give a course in social medicine in Vienna. He published the results of his researches on the "tendon reflexes," "acromegaly," "systemic disorders of the bones" and "diseases of carpenters and shoemakers"; also on "occupational diseases of the lungs," and he made valuable contributions also to anatomy and physiology. His diagnoses were famous for their accuracy. On the occasion of a reception in his honor, Professor Kundrat, the pathologic anatomist of Wieden Hospital (where Sternberg was the head of the department of internal medicine for thirty years) stated that he had always confirmed at necropsy the 100 per cent accuracy of Sternberg's clinical diagnoses. As chief physician of the large *krankenasse* of the Vienna *Genossenschaft der Gewerbetreibenden*, he was brought in contact with a large number of cases, from which he constantly enriched his medical knowledge. His passing leaves a wide gap in the medical profession of Vienna.

Prof. Dr. Reuss Summoned to Vienna

The pediatrician Prof. Dr. August von Reuss, a pupil of Escherich and Pirquet and who a few years ago was called from Vienna to the University of Graz, has been asked to take over the vacancy caused by the death of Dr. Moll and to serve as director of the Institute for Infants and Mothers in Vienna. This institute exerts a great influence on pediatrics in Austria. Modern welfare work took its inception from this institute, and Professor Reuss is an authority in this field. He plans to organize, within the department of social welfare, a center for welfare work among children, so that the general care of the younger generation and their welfare will be united in his hands.

Marriages

DANIEL MARVIN ADAMS JR., Panama City, Fla., to Miss Mary Thompson of Fort Lauderdale at Miami, September 24.

HAROLD CARL BOYLEN, Wheeling, W. Va., to Miss Audrey Carolyn Lucas of Louisville, Ky., at Wheeling, October 4.

PATRICIA HART DRANT, Philadelphia, to Mr. William Warren Rhodes of Wilmington, Del., August 18.

ROY DE VAUGHAN METZ, Detroit, to Miss Gussie Dean Gaston of Woodruff, S. C., September 24.

LEONARD DEWITT MURPHY, Buena Vista, Tenn., to Mrs. F. H. Brown of Nashville, September 29.

WILLIAM H. KERR to Miss Eula May Rossean, both of Hamburg, Iowa, at Sidney, September 5.

ALVIN F. COBURN, New York, to Miss Agnes Campbell Cooke of Paterson, N. J., October 2.

STEPHEN T. MANONG to Miss Marion Elizabeth O'Leary, both of New York, September 29.

JAMES DEVOTE PERDUE, Mobile, Ala., to Miss Ayrault Chapman of Jackson, July 25.

LOUIS I. GOLDBERG, Philadelphia, to Miss Julia Bredt of Mahanoy City, Pa., July 26.

JOHN R. RANKIN to Miss Vera Evalyn Langley, both of Keokuk, Iowa, September 8.

EDWARD H. FILES to Miss Grace Glass, both of Cedar Rapids, Iowa, September 8.

JOHANNES M. L. JENSEN to Miss Anita Netzwow, both of Milwaukee, September 15.

LUCY CAROL MILLER to Herbert Frank, D.D.S., both of New York, September 22.

GEORGE D. CALLAHAN to Miss Helen Anderson, both of Iowa City, August 22.

JOHN M. KARCH, Cincinnati, to Miss Rosemarie Brinck of Celina, Ohio, recently.

J. MALLORY KATLISLE to Miss Lillian Burt, both of Philadelphia, August 16.

Deaths

Bailey Kelly Ashford * Colonel, U. S. Army, retired, and professor of tropical medicine and mycology, University of Puerto Rico School of Tropical Medicine (Columbia University), died, November 1, at his home in San Juan, P. R. Colonel Ashford was born, Sept. 18, 1873, in Washington, D. C. He studied at the Columbian University, now known as George Washington University, and Georgetown University, where he received his medical degree in 1896 and the degree of doctor of science in 1911. In 1897 he entered the U. S. Army Medical Corps, in which he rose to the rank of colonel. In 1898 he went to Puerto Rico as a member of the military expedition, remaining during the United States occupation of the island, in command of medical department troops. In 1899 he recognized ancylostomiasis as the cause of the anemia prevalent among the rural population of Puerto Rico and in 1904 he founded the Puerto Rico anemia commission to carry on a campaign to combat that disease. Colonel Ashford also conducted extensive research on the etiology and treatment of sprue. The Institute of Tropical Medicine, which Colonel Ashford assisted in creating in 1911, led to the establishment in 1924 of the School of Tropical Medicine of the University of Puerto Rico in affiliation with Columbia University, in which school he continued as professor of tropical medicine. In 1933 both universities conferred honorary degrees on Colonel Ashford and the government of Puerto Rico placed the Ashford bust in the school as a memorial. During the World War he accompanied the first division to France as medical officer and later trained medical personnel at the front. Congress conferred on him the Distinguished Service Medal, while England conferred the Cross of St. George and St. Michael for services with the British. He was a fellow of the American College of Physicians and the American College of Surgeons, a member of the American Society for Clinical Investigation, the Association of American Physicians and Association of Military Surgeons of the United States, past president of the American Society of Tropical Medicine, and honorary member and past president of the Medical Association of Puerto Rico. In 1910 Colonel Ashford was a delegate from the United States to the International Congress of Industrial and Alimentary Hygiene in Brussels. In 1916 the Rockefeller Foundation appointed him a member of the medical commission to Brazil and in 1928 delegate to the International Congress of Tropical Medicine and Hygiene at Cairo, Egypt. He was the author of "Anemia in Puerto Rico," "Uncinariasis in Puerto Rico," "The Organization and Administration of the Medical Department in the Zone of the Armies" (Keen's Surgery, volume VII) and "Sprue" (Tice's Loose-Leaf Medicine, 1931) and editor of "Medical History of the World War."

William Scott Renner * Buffalo; McGill University Faculty of Medicine, Montreal, Que., Canada, 1884; formerly professor of laryngology, Niagara University Medical Department, Buffalo, clinical professor of laryngology and associate professor of otolaryngology, University of Buffalo School of Medicine; member of the American Academy of Ophthalmology and Oto-Laryngology, American Laryngological Association, American Laryngological, Rhinological and Otolological Society and American Otolological Society; fellow of the American College of Surgeons; past president of the Buffalo Academy of Medicine; at various times on the staffs of the Buffalo Eye and Ear Infirmary, Buffalo Children's Hospital, Sisters of Charity Hospital, Deaconess Hospital, Emergency Hospital, Mercy Hospital, Memorial Hospital, Buffalo City Hospital and the Erie County Hospital, Buffalo, and the J. N. Adam Hospital, Perrysburg, N. Y.; consulting specialist in diseases of the ear, nose and throat, U. S. Public Health Service and the U. S. Veterans' Bureau; aged 73; died, October 10, of bronchopneumonia.

BAILEY KELLY ASHFORD, M.D.
1873-1934

John Rich McDill, Cornwall-on-the-Hudson, N. Y.; Rush Medical College, Chicago, 1885; a founder of the American College of Surgeons; a founder and past president of the Manila (P. I.) Medical Society; past president of the Philippine Islands Medical Association; formerly professor and head of the department of surgery, University of the Philippines College of Medicine, and associate professor of surgery at his alma mater; veteran of the Spanish-American and World wars; chief medical officer of the Federal Board for Rehabilitation of Disabled Soldiers, with rank of assistant surgeon general, U. S. Public Health Service, 1919-1921; chief medical consultant to the U. S. Veterans' Bureau, 1922-1923, and for many years medical officer in charge of the U. S. Veterans' Hospital, Waukesha, Wis.; organized and became chief surgeon to the Woman's Hospital, Manila, in 1902 and St. Paul's Hospital, Manila, 1905-1910; chief surgeon to the Philippine General Hospital, 1910-1912; author of "Tropical Surgery"; aged 74; died, September 14, in the Cornwall (N. Y.) Hospital.

James Cornelius Wilson * Philadelphia; Jefferson Medical College of Philadelphia, 1869; emeritus professor of the practice of medicine and clinical medicine at his alma mater; past president of the Philadelphia County Medical Society, the American Academy of Medicine, the Association of American physicians, the American Climatological Association, the American Therapeutic Society and the College of Physicians; at various times on the staffs of the Pennsylvania Hospital, Jefferson Medical College Hospital, Lankenau Hospital, Philadelphia Lying-In-Charity Hospital, Rush Hospital for Consumptives, Jewish Hospital and the Bryn Mawr (Pa.) Hospital; author of "The Summer and Its Diseases," "A Treatise on the Continued Fevers," "Fever-Nursing," and "A Hand Book of Medical Diagnosis"; editor of "American Text-Book of Applied Therapeutics"; aged 87; died, October 28, of chronic myocarditis.

John Edward Clark, Detroit; University of Michigan Medical School, Ann Arbor, 1877; member of the Michigan State Medical Society; emeritus professor of chemistry and formerly dean of the department of pharmacy and professor of chemistry and toxicology, Detroit College of Medicine; professor of general chemistry and physics, Michigan College of Medicine, 1879-1885; at one time member and president of the board of education; for many years chemist for Wayne County; author of "Clark's Physical Diagnosis and Analysis," and "Laboratory Technique for Medical Students"; aged 84; died, September 19.

John Williams Coon, Stevens Point, Wis.; Jefferson Medical College of Philadelphia, 1884; past president of the Mississippi Valley Conference on Tuberculosis and the Milwaukee County Medical Society; professor of hygiene at the Milwaukee College of Physicians and Surgeons, 1897-1904; superintendent of the Milwaukee County Hospital, 1906-1908, Wisconsin State Sanatorium, 1909-1914, and the Municipal Tuberculosis Sanitarium, Chicago, 1914-1915; medical director of the River Pines Sanatorium; aged 74; died, September 17, of bronchopneumonia, arteriosclerosis and thrombosis.

Edwin J. Norris, St. Louis; St. Joseph (Mo.) Medical College, 1888; Marion-Sims College of Medicine, St. Louis, 1891; formerly instructor in ophthalmology, associate professor of ophthalmology and professor of ophthalmology, St. Louis College of Physicians and Surgeons, and instructor in clinical ophthalmology, National University of Arts and Sciences Medical Department, St. Louis; aged 67; died, September 26, in the Deaconess Hospital, of pneumonia.

Philip Henry Stewart, Paducah, Ky.; University of Louisville School of Medicine, 1890; president of McCracken County Medical Society; member and past president of the Kentucky State Medical Association; past president of the Walnut Log Medical Society; fellow of the American College of Surgeons; served during the World War; aged 66; on the staffs of the Illinois Central Hospital and the Riverside Hospital, where he died, October 8, of brain tumor.

Earle Stanley Green * Muncie, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; past president of the Delaware-Blackford Counties Medical Society; served during the World War; at one time secretary of the city board of health; for many years on the staff of the Home Hospital, now known as the Ball Memorial Hospital; aged 51; died suddenly, October 11, of coronary occlusion.

William Walling Van Dolsen * Philadelphia; Atlantic Medical College, Baltimore, 1909; Medico-Chirurgical College of Philadelphia, 1914; served during the World War; on the staffs of the Graduate, Germantown, Jewish, Mount Sinai and St. Agnes hospitals and the West Philadelphia Hospital for Women; aged 47; died, October 3, of heart disease.

Seldom Burden Overlock * Pomfret, Conn.; Bellevue Hospital Medical College, New York, 1889; member of the New England Surgical Society; fellow of the American College of Surgeons; at one time councilor of Windham County; surgeon in chief to the Day Kimball Hospital, Putnam; aged 74; died, October 8, of heart disease.

David Irvine Christopher, Colorado Springs, Colo.; Bellevue Hospital Medical College, New York, 1874; member of the Colorado State Medical Society; aged 88; on the staffs of the Union Printers' Home and Tuberculosis Sanatorium and St. Francis Hospital, where he died, September 30, of carcinoma of the tongue.

Friend Bennett Gilpin, Cranford, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1901; member of the Medical Society of New Jersey; veteran of the Spanish-American and World wars; aged 57; on the staff of the Elizabeth (N. J.) General Hospital, where he died, October 2, of heart disease.

Charles Daniel Easton * New York; Harvard University Medical School, Boston, 1904; member of the Rhode Island Medical Society; served during the World War; formerly on the staff of the Newport (R. I.) Hospital; aged 58; died, October 4, in the New York Hospital, of carcinoma of the rectum.

John C. Furlong, Spring Grove, Ill.; Rush Medical College, Chicago, 1891; member of the Illinois State Medical Society; past president of McHenry County Medical Society; aged 71; died, October 8, in the Mercy Hospital, Janesville, Wis., of injuries and shock following an automobile accident.

W. Bean Moulton * Portland, Maine; Johns Hopkins University School of Medicine, Baltimore, 1903; fellow of the American College of Surgeons; on the staffs of the Maine General Hospital and the Children's Hospital, Portland, and the Webber Hospital, Biddeford; aged 57; died, September 14.

Harry Franklin Coffman * Keyser, W. Va.; College of Physicians and Surgeons, Baltimore, 1913; formerly secretary of the Grant-Hampshire-Hardy-Mineral Counties Medical Society; aged 51; died, October 9, in the Memorial Hospital, Cumberland, Md., of septicemia following an infected tooth.

Calvin Rhea, Thayer, Mo.; Missouri Medical College, St. Louis, 1882; member of the Missouri State Medical Association; past president of the Oregon County Medical Society; aged 72; died, September 29, in the Baptist Hospital, Springfield, of coronary thrombosis.

George Perry Campbell, Nacogdoches, Texas; University of Texas School of Medicine, Galveston, 1911; member of the State Medical Association of Texas; aged 46; on the staff of the City Memorial Hospital, where he died, September 27, of typhus fever and pneumonia.

Charles Radcliffe Johnson * Batavia, N. Y.; Columbian University Medical Department, Washington, D. C., 1897; on the staff of the Veterans' Administration Facility; aged 62; died, September 24, of arteriosclerosis, cerebral hemorrhage and bronchopneumonia.

Charles Howard McDevitt * Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1900; lecturer on orthopedics, Temple University School of Medicine; aged 58; clinical assistant at the Temple University Hospital, where he died, September 11.

James Warren Hamilton, Mount Vernon, Ill.; Barnes Medical College, St. Louis, 1895; member of the House of Delegates of the American Medical Association, 1914-1915; member of the Illinois State Medical Association; aged 63; died, August 24.

George Hayward Nichols, Providence, R. I.; University of the City of New York Medical Department, 1886; aged 76; died, July 31, in the Jane Brown Memorial Hospital, of carcinoma of the large bowel, cardiorenal disease and intestinal obstruction.

Arthur Gilbert Harrison, Searcy, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Arkansas Medical Society; past president of the White County Medical Society; aged 59; died, October 5, in the Baptist Hospital, Memphis.

Harvey Samuel Cook, Valparaiso, Ind.; Chicago College of Medicine and Surgery, 1913; member of the Indiana State Medical Association; city health officer; member of the city council; served during the World War; aged 46; died, September 1.

Gilman Osgood * Rockland, Mass.; Bellevue Hospital Medical College, New York, 1886; member of the House of Delegates of the American Medical Association, 1915-1916, 1918 and 1920; aged 71; died, September 8, of milary tuberculosis.

William A. Ellison, Augusta, Ga.; Maryland Medical College, Baltimore, 1904; member of the American Psychiatric Association; clinical director of the Veterans' Administration Facility; aged 51; died, September 22, of carcinoma of the kidney.

Herman Earhart Almes * Chicago; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1889; Western Pennsylvania Medical College, Pittsburgh, 1890; aged 66; died, October 13, of carcinoma.

Robert Hardy Trammell, Excelsior Springs, Mo.; Medical College of Alabama, Mobile, 1887; served during the World War; aged 71; died, October 2, in the Veterans' Administration Facility, of cardiorenal disease and arteriosclerosis.

William Walton Lowe, Gillett, Ark.; St. Louis University School of Medicine, 1903; member of the Arkansas Medical Society; for many years president of the school board; aged 58; died, September 23, of heart disease.

Flora Adams * Hackensack, N. J.; Cornell University Medical College, New York, 1920; aged 42; on the staff of the Hackensack Hospital, where she died, October 20, of injuries received in an automobile accident.

Boris Margulis, Newark, N. J.; Universität Bern Medizinische Fakultät, Bern, Switzerland, 1916; aged 47; died, August 7, in the Beth Israel Hospital, of myocarditis and cardiovascular renal disease.

Leon Joseph Witkowski * Chicago; Northwestern University Medical School, Chicago, 1907; on the staff of the Englewood Hospital; aged 51; died, October 14, of cerebral emboli and renal calculus.

Thomas Herbert Allen * Lake Mahopac, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1875; aged 80; died, September 22, of carcinoma of the liver.

Irving Jewell Fisher * Newton, Mass.; Harvard University Medical School, Boston, 1900; on the staff of the Newton Hospital; aged 56; died, August 30, in Liverpool, England, of intestinal obstruction.

George F. Darraeott, Houston, Miss.; Memphis (Tenn.) Hospital Medical College, 1906; member of the Mississippi State Medical Association; aged 55; died, September 17, of coronary thrombosis.

William Orlando Martin, Philadelphia; Medico-Chirurgical College of Philadelphia, 1898; member of the Medical Society of the State of Pennsylvania; aged 64; died, October 3, of edema of the lungs.

Solon C. B. Fogel, Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1874; member of the Medical Society of the State of Pennsylvania; aged 84; died, August 26.

Ernest Albert Creighton * Red Cloud, Neb.; Western University Faculty of Medicine, London, Ont., Canada, 1898; president of the Webster County Medical Society; aged 63; died, August 7.

Joseph James Harrison Jr., Loudon, Tenn.; Chattanooga (Tenn.) Medical College, 1899; medical director of a sanatorium bearing his name; aged 57; died, October 7, of cerebral hemorrhage.

Arthur Seymour Alderson, Thayer, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1906; aged 64; died, October 3, in St. John's Hospital, Springfield, of cerebral hemorrhage.

Don C. Hughes * Findlay, Ohio; College of Physicians and Surgeons, Baltimore, 1893; aged 63; on the staff of the Home and Hospital, where he died, September 25, of cerebral hemorrhage.

Amzi Wolfe Hon, Los Angeles; University of Louisville (Ky.) School of Medicine, 1892; served during the World War; aged 66; died, September 29, of atrophic cirrhosis of the liver.

G. I. Jackson, Harrison, Ark. (licensed in Arkansas in 1903); member of the Arkansas Medical Society; aged 57; died, September 13, in Everton, of pneumonia and angina pectoris.

Don A. Barnhart, Huntsville, Mo.; Marion-Sims College of Medicine, St. Louis, 1895; member of the Missouri State Medical Association; aged 67; died, September 19, of heart disease.

John Joseph Murphy, Sioux City, Iowa; John A. Creighton Medical College, Omaha, 1911; member of the Iowa State Medical Society; aged 48; died, September 20, of erysipelas.

Joseph Austin Kilbourn @ Hartford, Conn.; College of Physicians and Surgeons, Baltimore, 1897; aged 73; died, October 13, of a hemorrhage from a ruptured esophageal varix.

Joseph Milton Weaver @ Allentown, Pa.; Medico-Chirurgical College of Philadelphia, 1906; for many years on the staff of the Allentown Hospital; aged 52; died, October 6.

James F. McDougal, Forrest City, Ark. (licensed in Arkansas in 1903); aged 74; died, September 11, in the Gartly-Ramsay Hospital, Memphis, Tenn., of heart disease.

William George Jacobs, Cincinnati; Miami Medical College, Cincinnati, 1903; served during the World War; aged 55; died suddenly, September 26, of cerebral hemorrhage.

William B. Kreider, Goshen, Ind.; Chicago Homeopathic Medical College, 1879; past president of the Elkhart County Medical Society; aged 85; died suddenly, August 28.

Percy Scott Richardson @ New Rochelle, N. Y.; Howard University College of Medicine, Washington, D. C., 1923; aged 35; died suddenly, October 3, of heart disease.

George R. Bowers, Knoxville, Tenn.; Lincoln Memorial University Medical Department, Knoxville, 1915; aged 52; died, September 27, of a self inflicted bullet wound.

John Carlos Hick, Eldorado, Ill.; Barnes Medical College, St. Louis, 1903; member of the Illinois State Medical Society; aged 59; died, October 3, of cerebral hemorrhage.

Alexander W. Davidson, Poplar Bluff, Mo.; American Medical College, St. Louis, 1876; formerly mayor of Poplar Bluff; aged 81; died, September 14, of nephritis.

David A. McEwen, Ogdensburg, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., 1895; aged 71; died suddenly, August 25, of cerebral hemorrhage.

Francesco Carlucci @ New York; Regia Università di Napoli, Facoltà di Medicina e Chirurgia, 1889; aged 70; died suddenly, October 1, of coronary thrombosis.

Herbert Charles Haskins, Manitou Beach, Mich.; Toledo Medical College, 1896; aged 80; died, September 16, of acute nephritis, aortic stenosis and endocarditis.

Archibald A. Booth, Jackson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1875; formerly county health officer; aged 83; died, August 17.

Clarence Maris, Columbus, Ohio; Starling Medical College, Columbus, 1881; aged 81; died, September 27, in St. Anthony's Hospital, of heart disease.

Thomas William Causey, Lakeland, Fla.; College of Physicians and Surgeons, Baltimore, 1909; aged 57; died, September 18, of coronary occlusion.

Ernest Wolfgang Hammes, St. Paul; Rush Medical College, Chicago, 1882; aged 79; died, in October, at St. Joseph's Hospital of cerebral arteriosclerosis.

James W. Overpeck, Hamilton, Ohio; Pulte Medical College, Cincinnati, 1882; aged 83; died, October 8, of carcinoma with metastasis and arteriosclerosis.

William H. Hamersly, Wilkes-Barre, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1883; aged 72; died, September 22, of appendicitis.

Willis Jay Redfield, Omaha; John A. Creighton Medical College, Omaha, 1900; aged 57; died, September 22, of hypertension and cerebral hemorrhage.

Erneste Augustus Johansen @ San Francisco; Jefferson Medical College of Philadelphia, 1892; aged 68; died, September 9, of coronary occlusion.

Leonard B. Bean, Hartford, Ky.; Baltimore University School of Medicine, 1904; aged 79; died, September 23, of arteriosclerosis and pericarditis.

Albert O. Hollie, Chicago; Chicago College of Medicine and Surgery, 1911; aged 53; died, October 14, of gastric ulcer and hemorrhage and nephritis.

Albert Llewellyn Tilton @ Los Angeles; University Medical College of Kansas City, Mo., 1899; aged 63; died, August 31, of angina pectoris.

Richard Calvin Bromley, Flat Woods, Tenn.; University of Nashville Medical Department, 1902; aged 63; died, October 4, of cerebral hemorrhage.

Edmond Lewis Wyman, Manchester Center, Vt.; New York Homeopathic Medical College, 1875; bank president; aged 91; died, September 27.

Roy H. McKnight, Kansas, Ill.; Dearborn Medical College, Chicago, 1906; aged 52; was found dead, October 1, of a self inflicted bullet wound.

Thomas Smith Pitt, Oxford, Mass.; Baltimore University School of Medicine, 1887; aged 70; died, August 10, of gastric hemorrhage and carcinoma.

James Hancher Hawkins, White Pine, Tenn.; Vanderbilt University School of Medicine, Nashville, 1888; aged 68; died, September 22, of uremia.

T. Chalmers Fulton @ Philadelphia; Jefferson Medical College of Philadelphia, 1880; died suddenly, September 27, of coronary thrombosis.

Herbert Leighton Fossey, Miami, Fla.; University of Tennessee College of Medicine, Memphis, 1920; aged 41; was found dead, August 17.

Marcus De Lafayette Jordan, Velasco, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; aged 64; died, August 15.

Charles Elias Frain, Haliburton, Ont., Canada; University of Toronto Faculty of Medicine, 1916; aged 40; was drowned, August 14.

John J. Plumer, Hailey, Idaho; Starling Medical College, Columbus, 1882; formerly bank president; aged 74; died, October 4, of nephritis.

Cornelius Thomas Hurley, Boston; College of physicians and Surgeons, Boston, 1905; aged 52; died, September 24, of coronary sclerosis.

Homer Mantz Steifer, Chico, Calif.; Baltimore University School of Medicine, 1895; aged 79; died, August 5, of cerebral hemorrhage.

William L. Bandy, Sedalia, Mo.; American Medical College, St. Louis, 1884; aged 77; died, September 30, of cerebral hemorrhage.

Anna Louisa Kuhn, Baltimore; Baltimore Medical College, 1883; aged 74; was found dead, October 7, of cerebral hemorrhage.

Elmer Edgar Grable, Chicago; National Medical University, Chicago, 1909; aged 73; died, October 17, of carcinoma of the liver.

Lewis Sutton Aspey, Scottsdale, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1899; aged 64; died, September 14.

William C. Bryant, Atlanta, Ga.; Southern Medical College, Atlanta, 1889; aged 67; died, September 13, of coronary occlusion.

Elwood Eugene Arnold, Los Angeles; Starling Medical College, Columbus, 1895; aged 67; died, October 3, of coronary sclerosis.

Josephus Myers, Alton, Ind.; Kentucky School of Medicine, Louisville, 1877; aged 83; died, September 12, of myocarditis.

Charles Harrell, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1904; aged 60; died, October 1, of heart disease.

Arthur R. Hill, Interlaken, N. Y.; Eclectic Medical Institute, Cincinnati, 1879; aged 80; died, October 16, of heart disease.

R. H. Cowan, Wytheville, Va.; Medical College of Virginia, Richmond, 1876; died, September 16, of organic heart disease.

William Paul McCulloch @ Cheswick, Pa.; Kentucky School of Medicine, Louisville, 1891; aged 71; died, September 17.

Frank Ernest Howard @ Olean, N. Y.; Trinity Medical College, Toronto, 1894; aged 63; died, July 3, of heart disease.

Edward Francis Scanlon, Scranton, Pa.; College of Physicians and Surgeons, Baltimore, 1890; aged 78; died, August 21.

Leonidas Forrest Moore, Stonewall, Okla.; Hospital College of Medicine, Louisville, 1907; aged 66; died, September 2.

William August Shafer, Chattanooga, Tenn.; Chattanooga Medical College, 1893; aged 63; died, August 30.

Bureau of Investigation

DAVID INGRAM

A Swindler Who Has Long Worked in the Medical Field Goes to Jail

Each of two young colored women of Chicago who answered a classified advertisement for a "registered nurse" that was run in the *Chicago Tribune* August 1, 2 and 3 has been awarded \$50 by the *Tribune* for helping to bring to justice a swindler who used the want-advertisement columns to obtain money under false pretenses.

The swindler in question is David Ingram, a colored man, who for some years has been posing as a physician. Ingram advertised in the *Tribune* that he wanted a registered nurse in connection with a proposed clinic to be opened in Chicago. Each of the two young colored women who received the *Tribune* award answered the advertisement and were engaged by Ingram for the position. Ingram required each to put up \$25 cash bond "to cover possible breakage of delicate instruments." One of the young women later became suspicious and notified the police, who issued a warrant for Ingram, charging him with obtaining money fraudulently. Ingram disappeared, but was arrested on August 13 at the instance of the other young colored woman who had put up a bond. Ingram was sent to the Psychopathic Hospital, but was declared sane, and on August 31 Municipal Judge N. J. Bonelli found this swindler guilty and sentenced him to the county jail for one year.

The Bureau of Investigation of the American Medical Association has long had a record of Ingram. In May, 1924, Ingram was arrested, convicted and sentenced to six months' imprisonment in Detroit for practicing medicine without a license. The Department of Health of the City of Detroit at that time sent the American Medical Association some voluminous extracts of testimony taken during the trial of Ingram. At that trial Ingram testified that he was a graduate of the National University of Argentina. As a matter of fact, he is not a graduate in medicine at all, and is grossly ignorant of all things medical. The latter fact was brought out at the trial just mentioned when, on cross-examination made for the purpose of testing his knowledge of medicine, he declared that streptococci was a foreign remedy that went into medicines; that the position of the fallopian tubes depends on "what you were making an examination for"; that the period of gestation "logically depends on the diagnosis of the general system," and that seminal vesicles could be found in females. As a result of this cross-examination, Ingram's own attorney at the time told the court that he had advised Ingram to change his plea from "Not Guilty" to "Guilty." He changed it and was sent to prison for six months.

In December, 1928, the Connecticut State Department of Health at Hartford telegraphed the Bureau of Investigation for all information available on Ingram. This was sent. It was then reported by that Department that Ingram was at that time located in Waterbury, Conn., where he had rented a house and bought certain equipment on the installment plan, that he was also mixed up in some sort of "health institute" and was believed to be attempting to sell shares. The man had claimed that he had also practiced medicine in Camden, N. J., and in Philadelphia, as well as in Chicago. In the Connecticut case Ingram again pleaded guilty and was fined \$100 and costs and given a thirty-day jail sentence.

In January, 1930, the Rochester Chamber of Commerce wrote to the Bureau of Investigation for information on Ingram, who was described as a colored man, "President and Treasurer of the People's Medical Laboratory" at New Brunswick, N. J. Ingram, it appeared, had turned up in Rochester for the alleged purpose of starting a branch of his business in that city. At that time Ingram claimed that his permanent address was in Chicago, although he was hazy about the details. The Rochester, N. Y., officials reported further that Ingram could neither read nor write English, could not spell the name of the street on which he claimed to have lived for five years in Chicago, did not know the name of the university in South America where he claimed to have had his training,

and was working the following racket: He would get the privilege from various pastors of colored churches to give an "educational" talk to the congregation. In these talks Ingram would discuss various diseases and tell the audience that the medicines he put up would cure them of such diseases. He would then go to a retail druggist and attempt to get the druggist to carry his line.

The next report received about Ingram was in April, 1930, from a Williamsport, Pa., physician, who reported that Ingram was in his town, having come there about two months previously and started to practice medicine. The Williamsport physician, who was a trustee and district councilor of the Medical Society of the State of Pennsylvania, notified the local police that the man was not licensed to practice medicine in Pennsylvania. The doctor also called on Ingram, who displayed a government license for alcohol, but no diplomas or licenses to practice.

In December, 1930, the Scranton (Pa.) Better Business Bureau reported that Ingram had been working his scheme in that city. He carried an advertisement in the classified pages of the local newspapers, calling for a "competent stenographer and bookkeeper." Girls who answered the advertisement were offered the position at \$30 a week, but were told that before they would be given the position, they would have to post a cash bond of \$150 to show their good intentions. Ingram was reported to have offered the same position to dozens of girls under the same terms. The Scranton Better Business Bureau further reported that Ingram, who also used the aliases "William Hillis" and "Dr. William Hill," was arrested by the Scranton police on three charges of issuing worthless checks. The Better Business Bureau reported that Ingram had been bound over to the Lackawanna County grand jury for arraignment in the January (1931) sessions. We have no record of the outcome of this case.

It is obvious from what has been written that Ingram is a confirmed swindler. For some months to come he presumably will be where his activities will be restricted. Presumably, also, as soon as he gets out of jail he will be up to his old tricks.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DELIVERY AFTER CESAREAN SECTION

To the Editor:—A woman, aged 40, has five children, 18, 16, 14, 9 and 3½ years of age. The weight of four was 10½, 11½, 9 and 10½ pounds at birth; all were normal deliveries except the last, when because of an hour-glass contraction of the uterus a cesarean section was done. The patient had never had any trouble during pregnancy before, except difficult labor at term. At present the patient is three months pregnant but is in very good health otherwise. What are the chances for having a normal delivery or would another cesarean section be indicated? Would therapeutic abortion be justifiable? Please omit name and address.

M.D., Texas.

ANSWER:—There is some difference of opinion as to whether or not delivery through the vagina should be permitted after a cesarean section. Some individuals believe that if a woman has had a cesarean section she should always be delivered by a cesarean section, chiefly because of the fear of rupture of the uterus during labor. On the other hand, most obstetricians are not of this opinion. Of course, if the reason for a cesarean section is a markedly contracted pelvis, all deliveries will have to be accomplished in the same way for full term babies. If, however, the indication for an abdominal operation was a temporary one, such as toxemia, contraction ring or some other complication, and this abnormality is not present at the time of subsequent confinements, it is not necessary to perform repeated cesarean section. This is especially true if the cesarean section was a low cervical one, because the incidence of rupture in a subsequent pregnancy or labor is very small. However, the incidence of rupture of the uterus after a classic operation is fairly high, especially if the patient is permitted to go into labor. Furthermore, many ruptures of the uterus after classic operations occur during pregnancy when the patient is unaware of danger and certainly not under the immediate observation of a physician. Since the incidence of uterine

rupture is far greater after classic operations than after the cervical operation, there is some justification for the dictum "Once a cesarean section always a cesarean section" for patients who have had classic cesarean sections. Regardless of which type of operation has been performed, if a woman is to be given a test of labor after one of these operations she should be in a hospital under close supervision from the onset of labor, but preferably for a few days before term. In the case cited there need be no fear of a recurrence of the hour glass contraction. More important factors to be considered are the type of cesarean section performed, the course of the convalescence, the height and duration of fever, and any complications that may have followed the operation. A febrile convalescence often means an improper healing of the uterine wound; but a normal, uncomplicated convalescence does not necessarily imply perfect union of the uterine incision. Therapeutic abortion is definitely not indicated simply on the basis of a previous cesarean section. If this woman had a classic cesarean section, the physician should seriously consider performing another cesarean operation and sterilizing the patient a few days before term. Elderly multiparas who have had more than five children have a relatively high mortality and morbidity when delivered vaginally even when they do not have the added factor of a uterine scar.

LATE CONGENITAL SYPHILIS

To the Editor—A boy, aged 7 years, presents the following conditions. The frontal bosses are prominent, he has typical Hutchinsonian teeth, there is complete optic atrophy of the left eye, and in the right eye there is choked disk of $1\frac{1}{2}$ diopters. Roentgen examination of the skull shows increased intracranial pressure, slight separation of the frontolambdoid suture, a shallow sella turcica and complete absence of the anterior clinoid process. Hearing in both ears is normal but there is some impediment of speech. The heart is apparently normal, the spleen is just palpable, the knee jerks are slightly exaggerated and there is some unsteadiness of gait. The Kolmer and Kline reactions are 4 plus. Spinal fluid examination was not permitted. Will you kindly outline a standard of treatment and also give the status of the use of stovarsol in this type of case. Please omit name.

M. D., Oklahoma.

ANSWER.—Although there can be no doubt from the presence of various stigmas and the positive serologic reactions that this child has congenital syphilis, it is not so certain that he has neurosyphilis. The physical and roentgen changes in the skull are compatible instead with the diagnosis of intracranial tumor. Every effort should be made to arrive at the correct differential diagnosis before starting on treatment for syphilis. Consultation with a neurosurgeon, serologic examination of the spinal fluid and ventriculography would seem to be essential. If the child has a brain tumor, it is unlikely to be gumma in spite of the fact that he is known to have syphilis. Brain gumma large enough to produce these signs of increased intracranial pressure is unusual in either the congenital or the acquired infection. If the necessary diagnostic procedures are refused, it would of course be highly desirable to treat the child for syphilis since there is at least some chance that central nervous system syphilis may be the correct diagnosis. No improvement of course is to be expected in the optic atrophy. If the choked disk is due to syphilis it should recede promptly within a few weeks of the institution of antisyphilitic treatment with the arsphenamines and potassium iodide. If it does not do so it may be assumed that the intracranial process is probably not syphilitic and the intervention of a neurosurgeon is imperative.

If, on further study, the lesion proves to be syphilis or if it is necessary to institute antisyphilitic treatment without further study, it would be preferable to begin with arsphenamine 0.2 Gm. or with silver arsphenamine 0.1 Gm. at intervals of five to seven days, combined with potassium iodide by mouth in a dosage of 1.3 to 2 Gm. three times daily. Six or eight weeks of this sort of treatment will serve as a therapeutic test. Therapeutic shock and the Herxheimer reaction need not be feared. If the lesion proves on examination or therapeutic testing to be due to syphilis, it would probably be desirable to consider the prompt institution of fever therapy with malaria, though a definite pronouncement cannot be made as to this without further information. Whether with or without induced malaria, treatment should be continued for a minimum of two years with alternating courses of an arsphenamine, preferably arsphenamine or silver arsphenamine, and a bismuth compound. The bismuth preparation should be an insoluble salt, preferably the salicylate, given for a child of this age in a dosage of 0.1 Gm. weekly.

The status of stovarsol in this type of case is not as yet determined. The use of this drug in the treatment of congenital syphilis is in the experimental stage and at present is not recommended.

PREGNANCY, VASOMOTOR RHINITIS AND ALLERGY

To the Editor—A married woman of 24 with a questionable allergic family history has been complaining of sneezing, watery nasal discharge and nasal congestion, without itching or congestion of the eye or palate, for nine months. A somewhat similar attack occurred in childhood, at which time she was told of a deviated septum and improved rapidly with local nonoperative treatment and has been symptom free to the present time. The patient is now four months pregnant and has noted a general aggravation of symptoms in the past four months. She is now being treated by a rhinologist, who finds a deviated septum and two small polyps, with some objective improvement in the nasal mucous membranes but with little subjective improvement except for slight decrease in sneezing. I would appreciate a discussion and references to the literature, especially on the following points: Relation of symptoms to pregnancy; would you consider the aggravation of symptoms by pregnancy in favor of an allergic basis? Advisability and dangers of skin testing and specific treatment during pregnancy. Kindly omit name.

M. D., New York.

ANSWER.—The symptoms described in this case suggest the diagnosis of vasomotor rhinitis, or, as it is also known, hyperesthetic rhinitis, hypersensitive rhinitis or perennial hay fever. If definitely allergic, a better title would be allergic rhinitis.

The following observations, if present, would be diagnostic of allergy: (1) a history of some other allergic condition in the patient, e. g., urticaria, asthma, migraine, or gastrointestinal upsets due to specific foods, (2) a history of one or other allergic conditions in the family, especially the parents; (3) eosinophilia in the nasal secretion, from 25 to 100 per cent of the cells in allergic individuals are commonly found to be eosinophilic leukocytes (4) presence of a blood eosinophilia in many cases, i. e., over 4 per cent; (5) relief of symptoms from instillation of ephedrine or epinephrine, and (6) positive skin tests corroborated clinically. These skin tests are important and should be carried out completely with all antigens with which the patient comes in contact, such as pollens, epidermals, foods and miscellaneous substances, including orris root, house dust and cottonseed. The more the foregoing are positive, the surer is the diagnosis of allergy.

There seems to be no special reference in the literature regarding the relationship of pregnancy and vasomotor rhinitis. However, much work has been done on the relationship of pregnancy to bronchial asthma and hay fever, and as these belong to the same group as do most cases of vasomotor rhinitis, what follows will almost certainly apply to all three conditions.

The fact that the symptoms in this case have been aggravated by pregnancy would not be helpful at all in diagnosing an allergic basis. All evidence points to the fact that there is a definite relationship between allergic conditions, especially bronchial asthma, and pregnancy, but in most of the reported cases the patient is either better during pregnancy or entirely free from symptoms during this time, with a return of attacks after delivery. Occasionally the attacks of asthma occur during pregnancy. The latter would seem to be definitely related to sensitivity to some sex hormone. Bradford Green (Bronchial Asthma as a Complication of Pregnancy, *THE JOURNAL*, Feb. 3, 1934, p. 360) reports two cases of pregnancy complicated by asthma, one ending fatally during a severe paroxysm. He concludes that there are two groups of cases: (1) asthma due to pollens, proteins or some focus of infection, in which there was preexisting asthma with aggravation of attacks during pregnancy or in which attacks were first noted during pregnancy but continued after parturition, and (2) asthma due to sexual cycle disturbance, with subdivisions into cases in which attacks occurred at each menstrual period and were relieved during pregnancy and lactation and those in which attacks occurred only during pregnancy, with freedom from attacks when not pregnant. In Green's article there is an extensive bibliography.

Coca (in Asthma and Hay Fever, by Coca, Walzer and Thommen, Springfield, Ill., C. C. Thomas, 1931, pp. 189, 190, 203, 204, 341, 342) devotes considerable space to the relationship of pregnancy and menstruation to allergy and points out that most asthmatic women are worse just before and during menstruation and that most of these patients are better during pregnancy, though an occasional one will be worse or have symptoms only during pregnancy.

Fishberg (Ovarian Substance and Corpus Luteum in Asthma, *Med. & Surg.* 2:26 [Jan.] 1918) reported favorably on the giving of ovarian substance and corpus luteum in thirty cases of asthma. He notes that a common characteristic of this type of patient is a tendency to adiposity and scanty menstruation. Other investigators have not been able to obtain equally good results by such treatment in similar cases.

The question as to the dangers of skin tests in allergic patients who are pregnant may be answered simply: Cuta-

nous tests can be done quite safely in all cases. Intracutaneous tests can be done safely if previous negative cutaneous (scratch) tests have been carried out. It would seem inadvisable to start with intracutaneous tests in the presence of pregnancy. While unlikely, it is possible that a constitutional reaction might follow an intracutaneous test; such a reaction might involve a contraction of the smooth muscle of the uterus with termination of pregnancy. For this reason it is likewise advisable to inject antigens, e. g., pollen extracts, in pregnant women with the greatest of caution. It is far better to underdose than to overdose. Some clinicians treat pregnant hay fever and asthma patients by repeated skin tests of the offending protein or pollen instead of injecting extracts. This procedure is a good one, gives excellent results and is to be recommended.

INFECTION OF MOUTH AFTER INJECTION OF LOCAL ANESTHETIC

To the Editor.—A boy, aged 9 years 11 months, healthy, in good physical condition, somewhat overweight, of a family in good circumstances, had the lower left second temporary molar extracted, Jan. 29, 1934, a procaine infiltration about the root and mandibular nerve block being done. Two or three weeks later the family noticed a swelling in the left side of the face. The dentist admitted that he had four similar cases after extractions the same week. The dentist had had cultures taken of his stock Ringer's solution, which was used at the time, and a rich mycelium growth resembling *Epidermophyton eruris* was obtained. Also the first of these cases to present itself had been treated by lancing and the packing showed the same fungous growth. About six weeks later the boy's mother returned from a prolonged absence and became alarmed with the situation. She brought him to me, April 16. At that time he seemed in good condition and showed no signs except locally, not even the regional lymphatics being involved. There was a firm mass, possibly cystic, the size of a hickory nut, in the gum tissue on the outer side of the jaw below the missing tooth, and one of similar size in the left cheek just in front of the angle of the jaw. There was no tenderness, edema or redness. I advised no treatment until more could be found out. I checked the story with the dentist and the laboratory man. The other cases are proving baffling to other physicians consulted. The dentist informs me that the incised mass in the one case was not benefited, that heat and massage seemed to aggravate another, and that two cases seemed to be gradually improving under no treatment. I have not observed these cases and therefore cannot judge this statement. Meanwhile a dentist, unknown to me, sent the boy to another dentist, who gave him daily treatments, locally, with a water-cooled ultraviolet machine. The boy was given seven daily treatments when the family again consulted me, and I advised stopping this treatment. There was no appreciable difference in the size of the masses, the skin of the cheek showed considerable erythema, and the boy was in a highly irate frame of mind. I understand on inquiry from an older dentist of great prestige in this community that the ultraviolet treatments are unjustified, as they have no authoritative standing as standard treatment. Are cases like this common? What is the probable condition, and what is the best treatment and management? What is the likelihood of these masses completing reabsorbing in time? Kindly omit name.

M.D., Pennsylvania.

ANSWER.—Fungous infections of the mouth are not uncommon, although most of them are superficial. Infections deep in the soft tissues are quite rare and usually are caused by organisms of the actinomyces group. However, Hardgrove (*J. Am. Dent. A.* 19:483 [March] 1932) reported a case of monilia infection carried, in his opinion, into the tissues from the mouth by the needle used in making the anesthetic injection for the extraction of a single tooth. This infection ran a long and involved clinical course; large doses of potassium iodide, from 0.65 to 2 Gm. daily, were followed by improvement, but complete relief was obtained only after the use of neoarsphenamine. It was thought that a high protein diet contributed to this end. Castellani (*Fungi and Fungous Diseases*) states that fungi may attack any organ and system of the human body, the integumentary system being the most frequently and the nervous system the most rarely affected. The exact identification of the infecting organism is desirable in planning treatment; since the *epidermophyton* type mentioned is generally limited to infections of the external skin, the correctness of the diagnosis in this case must be questioned. However, such drugs as potassium iodide in large doses are commonly used. Vaccines made of the organisms isolated from the infected regions have been found beneficial in many cases. Surgical incision is without benefit, though excision may be successful, and ultraviolet radiation futile. Sterilized physiologic solution of sodium chloride and Ringer's solution and even distilled water, unless rigidly protected by aseptic methods, may contain noteworthy amounts of bacteria and kindred organisms after a few days. Best anesthetic practice implies daily sterilization of anesthetic solutions or sterilization in containers holding only one day's supply and discarded at the close of one day's use. As this is not an average practice in dental offices, it is a debatable matter whether the method used in these cases should be considered malpractice. Some of the milder infections of this character heal spontaneously.

SILICOSIS OR PULMONARY FIBROSIS

To the Editor.—In an industrial plant large quantities of the following formula were ground up and mixed by hand with shovels:

No. 1.	Calcium magnesium chloride	99 pounds
	Chromate of sodium	½ pound
	Liquor pitch	½ pound
No. 2.	Sodium chloride	49 pounds
	Calcium magnesium chloride	46 pounds
	Liquor pitch	5 pounds

Could workmen inhaling this dust contract a chronic poisoning or condition that might be called "calcicosis" or anything simulating the disease silicosis, affecting the air passages and lungs? Kindly explain results, if any, of such exposure, giving the effect of these chemicals on the mucous membrane. Please omit name.

M.D., West Virginia.

ANSWER.—Neither this dusty mixture nor any of its constituents will produce any characteristic dusty lung disease such as silicosis. Only silica (SiO_2) is capable of inducing silicosis, but any other mineral dust under conditions of prolonged and gross exposure may cause some increase in pulmonary fibrosis. If the relative potential harm of silica is rated as 100, these other nontoxic mineral dusts may be rated only on the order of 5 or 10. Moreover, the fibrosis is in itself not pathognomonic, since many other dusts, alkalis, acids or vapors may induce somewhat similar if not identical x-ray markings. However, it is recognized that harm other than pneumoconiosis may be brought by either or both calcium chloride and sodium chromate. The former, owing to its avidity for water, sometimes causes erosions of the mucous membranes. Septal perforations are well known as frequent. Through similar action, chemical dermatitis may arise. The chromium salt, while much more of an irritant, is here used in so much smaller quantities as to make a practical hazard doubtful. Septal perforations are the characteristic response to the presence of chromate dust along the nasal membranes. To a minor extent, sodium chloride dust may lead to low grade irritation of the nasal tissues.

TREATMENT OF PHLEBITIS

To the Editor.—Twenty months ago I treated a man, aged 23, for phlebitis of the left femoral and popliteal veins. Now he has a milder form of the condition and states that his recovery from the first attack was not complete, since on standing a considerable time he experiences a feeling of tiredness in his ankle; soon a painful sensation of tightness develops, which extends to the knee and later becomes a deep bursting sensation. He is then compelled to resort to a recumbent position, which gives relief though at times he has some cramping of the leg and thigh muscles at night. The present attack was caused by standing at his work six or seven hours a day for four weeks. The described symptoms and signs are accentuated. The tenderness is experienced only in a small area over the femoral vein about an inch below Poupart's ligament. The only superficial veins involved are those below the knee, and the dilatation is moderate. Measurement of the affected limb half way between the ankle and the knee and half way between Poupart's ligament and the knee showed it to be three eighths inch larger than its fellow. The degree of swelling would be somewhat less than the figures indicate because the left leg is normally slightly larger than the right. The pain and discomfort are greater than the swelling of the involved limb seems to warrant. The patient is otherwise in vigorous health. The Kahn reaction on the blood was negative. The treatment has included iodine therapy, rest and elevation of the limb. Where is the site of the insufficiency in the return circulation and what is its cause and treatment? Please omit name.

M.D., Illinois.

ANSWER.—The successful treatment of deep phlebitis of the lower extremities requires a great deal of patience on the part of both physician and patient. There are no data to show whether the thrombosis of the femoral vein occurred during or following an infectious disease, an operation or an injury. Assuming, however, that the patient had an elevated temperature during the first and perhaps during the second attack, a careful search for the source of infection should be made. An inflamed tonsil, a dental root infection or a chronic prostatitis may be important, not necessarily as the etiologic factor, but as superimposed infection, which maintains or reactivates the thrombophlebitis. Should a focus of infection be found, it should not be eliminated until the attack of phlebitis has subsided; an arbitrary period of three months may be necessary before it is safe to eliminate infective foci without the danger of reactivating the thrombophlebitis. A tonsillectomy undertaken during the course of a subacute phlebitis may give rise to a renewed massive thrombosis followed by pulmonary embolism. The temperature, pulse and white cell count are fairly good indicators as to the activity of the clot. The sedimentation test of red cells is most sensitive in the detection of latent infection but it is not always available. It is customary to keep such patients in bed about ten days after the evening pulse has returned to normal. The swelling of the leg can be reduced by elevation, continuous heat, 15 grains (1 Gm.) of ammonium nitrate three times a day and intravenous injections of salyrgan in doses of from 0.5 to 2 cc. at three day intervals. Others

prefer calcium gluconate (10 cc. of a 10 per cent solution) or sodium thiosulphate in the same amount. While the calcium prevents the formation of edema by an action on capillary permeability, the sodium thiosulphate is claimed to prevent further thrombosis by interfering with clotting factors. The salyrgan has been most satisfactory.

In the diet one should aim at a moderate dehydration, limiting the fluid intake to a quart of water, avoiding much salt and sugar and providing for a regular daily bowel movement. When the patient gets out of bed an adequate elastic support must be supplied, reaching to the groin. Soreness of the femoral vein or a neuritis, which often accompanies a pelvic phlebitis, may be alleviated by roentgen therapy in small doses (from 90 to 100 roentgens at intervals of ten days).

The venous block, if the edema is unilateral, is generally in the femoral and external iliac veins. Nothing is known that will safely prevent embolism except that after four to six weeks the clot is usually so firmly organized that it is not apt to break loose.

NEO-PROBILIN

To the Editor:—What may be said concerning the use of Neo-Probilin (Schering and Glatz, Inc.) in the correction of "biliousness" due to, as stated in the enclosed advertising folder, "dietetic errors, too much rich food, excess of coffee, tea, alcohol, exposure to cold and wet, overwork, great mental strain"?
M.D., Connecticut.

ANSWER.—A number of bile salt compounds have been actively promoted for a variety of disease conditions in recent years, of which Neo-Probilin, with the following formula, is typical:

Bile Salts Combined.....	1½ gr.
Sodium Salicylate.....	¼ gr.
Phenolphthalein	½ gr.
Menthol	⅓ gr.

The recommended dose is two tablets, twice a day. "Bilious" is a "term popularly applied to disorders supposed to arise from a too free secretion of bile." In the "Actions and Uses" section of New and Nonofficial Remedies dealing with bile salt compounds it is stated that "they stimulate the secretory activity of the liver, increasing both the fluids and solids of the bile." From these observations it would appear contrary to good therapeutics to administer bile salts for "biliousness," lest the condition be considerably aggravated. The mixture has another inconsistency however, according to a leading professor of therapeutics, who has written that "a dose of ½ gr. of sodium salicylate twice daily is a joke"; and so it would appear to be in view of the recommended U. S. P. dosage of 1 Gm., or 15 grains (or thirty times the amount of salicylate exhibited in a single dose of Neo-Probilin). The menthol is present in the similarly modest concentration of two fifths of the U. S. P. dose (0.06 Gm., or 1 grain). The same consultant has further stated that "¾ gr. of phenolphthalein twice a day will move any one's bowels."

Neo-Probilin, like many similar mixtures promoted under proprietary and noninformative, or therapeutically suggestive, names represents from a therapeutic point of view a combination of bile salts and phenolphthalein. That phenolphthalein is a valuable cathartic in cases in which no sensitivity exists cannot be doubted, but the possible occurrence, though relatively rare, of the hemorrhagic macular eruption that it occasionally produces should be borne in mind. Equally valuable in given conditions are the bile salt preparations, per se. There is, however, no pharmacologic justification for the joint administration of the two drugs, nor, of course, for the addition of sodium salicylate or menthol, particularly in such small concentration, and the medical profession is imposed on when it is asked to prescribe such a mixture under a proprietary name.

ALOPECIA AREATA

To the Editor:—A young woman has lost nearly all of the hair on her head, including the eyebrows. The Wassermann reaction is negative and I can find no cause for the trouble. I know there has been some work done in the realm of glandular therapy along this line and am asking you for any advice you may be able to give me. She is much worried over the matter, as she is practically bald. She has never had any serious sickness.
H. K. OWENS, M.D., Elkins, W. Va.

ANSWER.—The case referred to is apparently one of alopecia areata, which is a disease characterized by loss of hair in circumscribed, rounded patches and may involve the scalp alone, the scalp and other areas such as the eyebrows and beard, and rarely the entire integument, in which case the term alopecia totalis is used. The etiology cannot always be determined, but credence is given chiefly to neuropathic, parasitic and toxic origins. In alopecia areata spontaneous regrowth of hair may

occur in months or years; because of this fact it is difficult to evaluate treatment, and erroneous deductions may follow the introduction of new therapeutic measures. In recent years, claims have been made of successful treatment for alopecia areata by the administration of anterior pituitary orally and hypodermically and by subcutaneous implantation or oral administration of fresh whole anterior pituitary gland. Adequate scientific confirmation of such results following pituitary therapy appears to be lacking. Thyroid extract has been prescribed in alopecia areata and its use in cases exhibiting a low basal metabolism rate may be rational. Likewise, in certain instances, other forms of glandular therapy may be indicated for symptomatic treatment, though an etiologic relationship between glandular dysfunction and alopecia areata has not been definitely established.

While alopecia areata may occur in a syphilitic patient, in which case antisyphilitic treatment should be considered part of the management of the case, true syphilitic alopecia is more irregular or "moth eaten" in its appearance and usually occurs in early stages of the disease, in which case it is likely to be associated with other manifestations or history of syphilis and the Wassermann reaction is usually positive.

The accepted treatment of alopecia areata includes consideration of the local application of stimulating and parasitic lotions or ointments, ultraviolet ray exposures to produce active hyperemia, general tonic medication and symptomatic treatment, search for foci of infection, and attention to general hygiene and to the condition of the nervous system.

DENTAL CARIES OF MOTHER AND PROSPECTIVE CHILD

To the Editor:—Can you outline for me a reasonable program of medicine which, in addition to a reasonable diet, might be calculated to reduce the chances of dental caries in a woman, aged 30, now two months along in her second pregnancy? What hope may be held that such a program of diet and medicine might also insure the child against future dental caries? Is there any information now available which suggests that calcium, phosphorus and vitamins might have any adverse effect on either mother or fetus? Please omit name.
M.D., New York.

ANSWER.—During pregnancy there is an insufficiency of calcium and phosphorus in the maternal tissues, resulting from the demands of the growing fetus. Likewise during lactation the formation of milk reduces the calcium and phosphorus content of the maternal body. Hence these minerals must be supplied in sufficient quantities during pregnancy and lactation to cope with the demands of the fetus in utero and the nursing baby. If these minerals are not supplied in the food or as medicinal preparations, the mother suffers. Among the chief symptoms and signs of lack of calcium and phosphorus are dental caries, puffiness of the hands and face, tingling and numbness of the fingers and toes, and evidences of tetany such as muscle contractures, which produce severe pain, muscle weakness and exhaustion. The chief foods that contain calcium are milk, vegetables and prepared cereals. Eggs contain large amounts of phosphorus.

It is not only necessary to have abundant calcium in the diet but it is essential that the body be able to absorb and utilize this mineral. Absorption depends on the presence of ergosterol, which is normally present in the skin and which acts only in the presence of natural or artificial sunlight. Activated ergosterol (viosterol) helps in the absorption of calcium from the gastro-intestinal tract and in deposition of the calcium in the bones. The utilization of calcium by the body is dependent on the proper functioning of the parathyroid glands. From the foregoing it is apparent that a pregnant woman should include in her diet throughout pregnancy an abundance of milk, eggs, vegetables, fruits, butter, whole grain cereals and cod liver oil, haliver oil or viosterol. If the patient cannot drink three or four glasses of milk a day, calcium and phosphorus should be prescribed in tablet form. During the summer months the sunshine aids in the utilization of the calcium in the diet but in the winter months, in climates where sunshine is at a minimum, it is most important that a pregnant woman take viosterol or haliver oil every day. These preparations and a proper diet help the mother's teeth and also the teeth of the unborn child. The simplest way in which to administer viosterol is to prescribe capsules containing 3 minims of halibut liver oil with viosterol 250 D. These capsules, which have in them both vitamins A and D, are taken three times a day during the days with little sunshine and twice a day at other times. Calcium, phosphorus and vitamins even when given in fairly large amounts do not have any deleterious effects on the mother or baby. In addition to protecting the mother's teeth by diet and medication, it is important that a pregnant woman see a dentist at least twice during her pregnancy both

for the purpose of having the teeth properly cleaned and for the detection of early caries, cavities or brittleness.

Any advice given as to the diet of the expectant mother should be applied to the individual with discretion and should be definitely related to all the specific problems in the management of the case. In general the diet calculated to provide liberally for the bone needs of the growing child is also the best for adequate tooth development in the child and the prevention of decay in the mother. Mineral-containing foods, such as milk and milk products, should be used liberally. It is extremely difficult to supply enough calcium and phosphorus in any other way. Adequate, even generous, allowance should be made for vitamins, especially D. The energy-supplying foods, especially carbohydrates, should be reduced nearly to the minimum. It is most important to consult one's dentist during pregnancy for early diagnosis of tooth decay and prompt filling of the cavities while they are small. There are no specific indications for any form of medical treatment during this period and there is no reason to believe that the ingestion of calcium, phosphorus and vitamins within the foregoing limit can harm the mother or child. Such a program may have some effect in insuring the child against future dental caries, although it is of relatively little significance as compared with factors that are brought to bear on the child after birth and probably to a less degree with those that have to do with the hereditary background. High individual immunity to dental decay is probably no different in origin than the same kind of immunity to other diseases.

TREATMENT OF WASP STING

To the Editor:—I live in a community in which wasp and hornet stings are a common occurrence. I have used spirit of ammonia but find it unsatisfactory. Can you suggest a routine of treatment that will ease the sting without taking something by mouth? My patients see no connection in a wasp sting on the leg and a dose of bitter medicine by mouth. Please omit name.

M.D., Texas.

ANSWER.—The sting should be removed by lifting it out with the blade of a knife, not by grasping it to pull, for this may force more poison into the wound. Then the application of ammonia water will ease the pain. If the person is very susceptible and is stung on a limb, a constrictor should be placed proximal to the sting in order to prevent rapid absorption of the toxin.

Epinephrine may be injected locally in small amount. If a general reaction has already begun, larger doses, from 0.3 to 1 cc. of the 1:1,000 solution, may be given intramuscularly. Intravenous administration may be called for in severe cases, but the drug should be well diluted with physiologic solution of sodium chloride and given very slowly.

USE OF X-RAYS FOR ACNE

To the Editor:—Kindly give me the best method of treating acne of the face and back with x-rays. Is this a good method: distance 20 inches, time four minutes, 4 amperes, 100 kilovolts. Filter?

F. M. SANOIFER, M.D., Greenwood, Miss.

ANSWER.—X-rays should not be used therapeutically either for acne or for any other skin disorder until the apparatus has been carefully standardized and the factors for the erythema dose determined either by ionization or by visible skin effects. The erythema or skin unit dose that is the equivalent in modern terminology of 300 roentgens should be determined on the flexor surface of a young and fair-skinned individual. The various factors, such as anode skin distance, milliamperage, voltage and time, may be changed only if the operator is familiar with the arithmetical method of computing dosage and the biologic laws that apply to roentgen rays. MacKee advises as a practical unfiltered technic for the beginner the use of the following constants: 2 milliamperes of current, 100 kilovolts, a distance of 8 inches, and an exposure of three minutes to produce an erythema dose or 300 roentgens. In the treatment of acne an erythema dose should never be administered. The average dose should be one-fourth skin unit, forty-five seconds with the foregoing factors, once weekly. Some dermatologists even use one-eighth skin unit once a week. The number of treatments will depend on the severity of the acne and from eight to twelve treatments are usually necessary to obtain results. The skin should be carefully watched for signs of excessive dryness, wrinkling or erythema. Furthermore, x-rays should not be used in every form of acne and great care must be employed to avoid the use of irritating topical applications during the treatment. The average patient is better off if he can be cured of the acne without the use of x-rays. Also the average practitioner before he uses x-rays in the treatment of

cosmetic conditions should be well aware of the medicolegal aspects of the situation and should hesitate to do so without the proper training. MacKee's book on "X-Rays and Radium in the Treatment of Diseases of the Skin" should be consulted.

VASOMOTOR NEUROSIS OF MAMILLA

To the Editor:—In a recent issue of THE JOURNAL mention is made of "vasomotor neurosis of mamilla and cancer." Please let me know what mamillary vasomotor neurosis is and how it is recognized. What is its significance, if any, to other gynecologic problems? Omit name, please.

M.D., California.

ANSWER.—The vasomotor neurosis of the mamilla has been repeatedly described in the German literature of recent years. Zimmermann described the condition in 1920 under the term of spasm of the mamilla. It was later described by several others, and Colin (*Med. Klin.* 22:1988 [Dec. 24] 1926) designated the condition as vasomotor neurosis of the mamilla.

Zimmermann, Beck and Rodecourt made further reports on the condition in 1929 and 1931. Attention was called to Rodecourt's report by a brief abstract in THE JOURNAL, Jan. 9, 1932, page 183.

In Zimmermann's report (*Deutsche med. Wchnschr.* 55:1418 [Aug. 23] 1929) it is stated that the patients have attacks of pains of a spasm-like and cutting type, accompanied by paling, erection and hardening of the mamilla. Some reports mention a radiation of the pains to the axilla.

Most of the observers point out that exposure to cold is an eliciting factor. The vasomotor neurosis of the mamilla has been observed during pregnancy and during lactation, but also in virgins.

Most of the women in whom it develops have a neuropathic constitution, but it has also been observed in women who are entirely free from nervous irritability. A connection with the menstrual period has not been noted.

Beck has taken particular notice of the vasomotor neurosis of the mamilla in the last few years and has called attention to the possibility of a connection with tumors of the heart.

LOOSENESS OF SKIN OF NECK

To the Editor:—Will you please inform me if there is any worthwhile local treatment that can be prescribed for looseness of the tissues of the neck in a woman, aged 40? There is not any double chin and the patient is of medium weight, but the skin and neck tissue seem to sag more than usual. This does not follow any strenuous dieting with loss of weight but has occurred in a patient who has always been careful of her diet for fear that her weight might increase. Please omit name.

M.D., Ohio.

ANSWER.—Exercises to strengthen the neck muscles will improve the tone of the neck and reduce the laxness of the skin. These exercises are those of rotating, nodding and general body exercises such as swimming to strengthen the neck.

The skin and neck should be massaged and a good skin cream applied at night. In the morning after massage the neck should be douched with cold water.

This condition may be inherited and is often more marked in women who have had children.

In case the skin is very redundant, a plastic operation may be done but should be undertaken by a well trained surgeon only after other measures have failed.

INCONTINENCE OF URINE

To the Editor:—Would you be kind enough to tell me which is the best treatment for incontinence of urine in women? This is in reference to the case of a woman operated on for renal tuberculosis four years ago, who had very intense cystitis before the operation, cystitis which improved extraordinarily after the extirpation of the kidney. Now she has an incontinence of urine for which I desire to know the best treatment.

J. E. CAVELIER, M.D., Bogota, Colombia.

ANSWER.—In order to outline the best treatment, one must know a good deal more about the patient than the statement that she has an incontinence of urine.

Incontinence of urine in this patient may be due to tuberculosis of the bladder following tuberculosis of the kidney. On the other hand, what appears to be an incontinence may be due to the presence of infection in the other kidney. Before advising the best form of treatment, therefore, it will be necessary to examine the patient with a cystoscope to determine whether or not she has active tuberculosis in the bladder at this time and also to examine the remaining kidney with a ureteral catheter to determine the presence or absence of infection there. And, finally, a careful examination of her pelvis should be made to rule out disease in the pelvis. In other words, a patient with this symptom and this history needs a complete urologic study.

CELLULITIS OF PELVIC TISSUES

To the Editor.—A woman about 35 years of age has had one child, now 4 or 5 years old. At the time of this pregnancy she had a large fibroid tumor of the uterus. About two years ago she developed a pain in the right inguinopubic region and a fluid mass, which was operated on by another doctor, under local anesthesia. During the operation the sac broke and, according to the patient, nothing was removed, so I imagine that this was a hydrocele of Nuck. The pain continued the same after the operation. About three months ago I performed a supravaginal hysterectomy on account of the fibroid tumor, which weighed 6 pounds (2.7 Kg.) and filled the entire fundus uteri, and also removed the appendix. At the time of the operation I examined the right inguinal region internally and intramurally and could find nothing grossly pathologic that might be responsible for this pain. The pain still continues and is quite severe at times; it is not a steady pain; it seems to let up when the patient is sitting or standing and becomes worse when she lies down; it does not seem to make much difference what position she is lying in. Kindly suggest diagnosis and treatment. Please omit name.

M.D., Illinois.

ANSWER.—The most common cause of pain in cases of this character is cellulitis of the pelvic tissues with associated nerve involvement. The Elliott treatment, Priessnitz dressings, and other forms of hydrotherapy merit a trial. Codeine and acetyl-salicylic acid are preferable to morphine for relief of the pain. Further surgical intervention might well be considered if the distress continues.

ALCOHOLIC SOLUTION OF PHENOBARBITAL

To the Editor.—In reviewing your answer to the inquiry regarding "breast pain during menstruation" in *THE JOURNAL*, Sept. 30, 1933, page 1097, I notice your suggestion of alcoholic solution of phenobarbital or other sedatives. Please advise me why you suggest the use of alcoholic solution of phenobarbital instead of the powder or tablet form of phenobarbital. Please omit name.

M.D., South Carolina.

ANSWER.—The alcoholic solution of phenobarbital, commonly known as elixir of luminal or elixir of phenobarbital, is a widely used sedative which contains only one-fourth grain of the drug in each teaspoonful. It is preferable to the powder or tablet form chiefly because the dosage is smaller than is commonly available in solid form and because the amount administered may be readily increased or decreased to meet requirements.

SERUM SENSITIZATION

To the Editor.—I am treating a boy for a severe attack of scarlet fever. About two years ago he had an illness which another doctor diagnosed as scarlet fever and gave him a therapeutic dose of antitoxin. If I should give the boy antitoxin now is there any danger of anaphylaxis due to previous treatment? How long is sensitization generally supposed to last? Some years ago in a laboratory in Chicago I injected serum into the ear vein of a rabbit that had a similar treatment some weeks before. The rabbit died almost immediately, so since that time I have had a wholesome respect for serum sensitization.

F. J. HACKNEY, M.D., Centralia, Wash.

ANSWER.—There is danger of anaphylaxis. Sensitization may last indefinitely. It is possible to test for sensitization to horse serum by intradermal injection of a dilute solution of the antitoxin.

ASCITES WITH OVARIAN CARCINOMA

To the Editor.—I have an elderly patient with an ovarian carcinoma. On two occasions I have withdrawn 7 quarts of fluid from the abdominal cavity. Is it good surgery and safe to tie in a catheter the next time, if the dressings are aseptically changed? If not, why? If so, why can't it be done in any form of ascites?

M.D., Connecticut.

ANSWER.—It is not good surgery to leave a catheter in the peritoneal cavity for drainage of ascites. Regardless of the asepsis in changing the dressings it is impossible to avoid the development of infection around the catheter or any foreign body passing through the skin. There is little danger from repeated aspirations if reasonable care is used.

CALCIUM AS ANTIDOTE TO RESPIRATORY DEPRESSION

To the Editor.—For the respiratory depression following the intraspinal injection of magnesium sulphate, calcium chloride is used intravenously as an antidote. What is the physiologic chemistry involved in this antidotal effect? Has calcium chloride been used to overcome the respiratory depression of spinal anesthesia? In what respect would the use of calcium chloride vary in the two cases? Please omit name.

M.D., Nebraska.

ANSWER.—The essential nature of the antagonism is not understood. All that is known is that several electrolytes are required, in a certain ratio, in order that cells may perform their functions. The antagonism is strictly quantitative, excess

of calcium also acting as a depressant to nerve and muscle. Calcium chloride has probably not been used in attempts to overcome the respiratory depression in spinal anesthesia and it would be most surprising if it should be found of value, because this depression is due to the ascent of the anesthetic and intraspinal blockage of the nerve roots that supply the muscles of respiration. There is no evidence that calcium antagonizes the effect of local anesthetics on the substance of nerves.

RELIEF OF SCIATIC PAIN

To the Editor.—With focal infection eliminated so far as is possible, what is the best procedure for the relief of sciatic pain? What is the technic for injection of the sciatic nerve? What is the best solution for injection? Is this an office procedure? What internal medication is recommended? Please omit name.

M.D., Massachusetts.

ANSWER.—The treatment of symptomatic sciatic pain depends on the etiologic diagnosis. In this connection the recent work of Yeoman and of Freiberg and Vinke on the importance of the piriformis should be considered. The work of Danforth and Wilson should also be consulted.

For the symptomatic relief of pain one should consider caudal epidural injection, using 0.5 per cent solution of procaine hydrochloride, a pelvic belt, manipulation under anesthesia, and fusion operation.

Internal medication with 3 Gm. of sodium salicylate in tap water, by rectum, can be repeated at infrequent intervals to relieve pain.

DETERIORATION OF DIGITALIS

To the Editor.—Given a reliable preparation of digitalis leaves, will it retain most of its potency for six months when put up in "sealed" gelatin capsules? Please omit name.

M.D., New Jersey.

ANSWER.—It will.

MUSCLE CRAMPS DURING SLEEP

To the Editor.—I have been interested in the recent remarks on muscle cramps during sleep appearing in *Queries and Minor Notes*, first by a New York physician inquiring as to a possible cause, and in the issue of September 29 by Dr. C. A. Mills of the University of Cincinnati, who states that he has observed almost complete and very prompt relief by the administration of dilute hydrochloric acid. In line with this treatment is the advice by *THE JOURNAL* to the New York physician to give an acid salt such as ammonium nitrate.

I began a study of this common clinical condition about six months ago at the San Francisco Relief Clinic. I have studied to date fifteen patients. Thirteen of them had complete relief with calcium administered two to three times daily before meals. Calcium gluconate was used exclusively in all but one case. In this case calcium chloride was given and the gluconate substituted later. The two worked equally well. It is doubtful whether one of the two patients who failed to get relief should have been included in this study, since he had cramps not only in the legs but also in the hands and during the day as well as the night. He probably will be shown to have one of the better recognized types of tetany. The other failure was a man seen first about a week ago, who after one week had no relief whatever. He has not been thoroughly studied as yet. In addition to these fifteen patients, I have given calcium to perhaps eight other persons who complained of this condition, all of whom had equally prompt and good relief. These were friends and relatives who were not closely studied.

I have done fasting serum calcium determinations on three of this group with readings of 12, 12.2 and 13 mg. per hundred cubic centimeters. I am now engaged in estimating the diffusible-nondiffusible ratios in some of these patients. Estimation of the diffused calcium would undoubtedly be of greater value than that of the diffusible, but I am unwilling to do spinal punctures in the clinic, and so far I have not been fortunate enough to get any patients with this condition in the hospital. No phosphorus determinations have been done, but in view of the calcium readings they will probably be normal. Clot retraction has been normal in three cases studied.

The condition is common. It seems to be preponderately present in middle life and older age. Nearly all the patients have varicose veins. Diabetes has not been present in any of the fifteen studied. Several of the patients volunteered the information that they were much more apt to have cramps during a night following a day when they were on their feet an unusual lot or when they had an unusually hard day's work.

It was the usual thing to have a patient say he had relief after two or three doses.

Further studies done on these patients have included complete histories, physical examinations, urinalyses, blood Wassermann and Kahn tests, and particularly a careful examination of the peripheral circulation. A rather large percentage of the patients also had a symptomatic purpura, noted by the patients simply as a tendency to bruise. With the exception of this and the varicose veins, no condition was found with any undue frequency in the group.

In view of the equally good results obtained with calcium and acid salts, I have wondered whether the basic physiologic disturbance might not be a disturbance in the ionization of calcium.

This study is being enlarged and completed for publication at a later date.

ROBERT A. STEVEN, M.D., San Francisco.

Assistant in Medicine, University of California Medical School.

Connecticut July Examinations

Dr. Thomas P. Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held in Hartford, July 10-11, 1934. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Twenty-eight candidates were examined, 25 of whom passed and 3 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Yale University School of Medicine.....(1932)	79.7, 82.6, 83.5		79.3
George Washington University School of Medicine....(1933)			77
Georgetown University School of Medicine.....(1933)	76.5, 76.8, 80.2*		75.3
Howard University College of Medicine.....(1933)			76.4
Loyola University School of Medicine.....(1934)			75

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, June 30:

Hospitals Approved for Intern Training

St. Joseph Hospital, San Francisco.
St. Francis Hospital and Sanatorium, Colorado Springs, Colo.
St. Mary's General Hospital, Lewiston, Me.
Burbank Hospital, Fitchburg, Mass.
Providence Hospital, Holyoke, Mass.
Mercy Hospital, Springfield, Mass.
Bryan Memorial Hospital, Lincoln, Neb.
St. Joseph's Hospital, Yonkers, N. Y.
Valley Hospital, Sewickley, Pa.

Hospitals Approved for Residencies in Specialties

Denver General Hospital, Denver. Medicine and pathology.
Elgin State Hospital, Elgin, Ill. Psychiatry.
Spring Grove State Hospital, Catonsville, Md. Psychiatry.
Belchertown State School, Belchertown, Mass. Mental deficiencies.
Danvers State Hospital, Hathorne, Mass. Psychiatry.
Hastings State Hospital, Ingleside, Neb. Psychiatry.
Atlantic City Hospital, Atlantic City, N. J. Medicine-pediatrics and surgery-gynecology.
White Haven Sanatorium, White Haven, Pa. Tuberculosis.
Baroness Erlanger Hospital, Chattanooga, Tenn. Surgery.
Hopemont Sanitarium, Hopemont, W. Va. Tuberculosis.
Milwaukee County Hospital for Mental Diseases, Wauwatosa, Wis. Psychiatry.

Hospitals Approved for Additional Residencies

Gallinger Municipal Hospital, Washington, D. C. Ophthalmology-otolaryngology.
University Hospital, Ann Arbor, Mich. Urology, orthopedics, neurosurgery, thoracic surgery and tuberculosis.
New York Post-Graduate Medical School and Hospital, New York City. Ophthalmology, otolaryngology, pathology and radiology.
Good Samaritan Hospital, Cincinnati. Pediatrics.
City Hospital, Cleveland. Thoracic surgery, obstetrics, otolaryngology, ophthalmology and communicable diseases.
Pennsylvania Hospital, Philadelphia. Cardiology, medicine, pathology, radiology, surgery and urology.
Memphis General Hospital, Memphis, Tenn. Gynecology.
State of Wisconsin General Hospital, Madison, Wis. Neurology and urology.

Book Notices

The Ancestry of the Long-Lived. By Raymond Pearl and Ruth DeWitt Pearl. Cloth. Price, \$3. Pp. 168, with 21 illustrations. Baltimore: The Johns Hopkins Press; London: Oxford University Press, 1934.

This book brings together the products of an extensive statistical genetic study of longevity, most of which has been previously published in various numbers of *Human Biology* during the past four years. Chapters IV and IX contain largely new material. The method employed is that of comparing two groups of living persons (*propositi*), the longevous group and a more or less ordinary group, selected from the family history records gathered for other purposes by the department of biology. For convenience the latter group is called the FHR series. The two groups have one feature in common: all six immediate ancestors of the individuals in both series are dead, a necessity of the case if complete ages are to be known. The longevous group is made up of sibships containing at least one person 90 years of age or over and still living.

A new concept is introduced; namely, the total immediate ancestral longevity (called TIAL). This consists of the sum of the completed ages of the six immediate ancestors. The TIALS of the two groups—long series and FHR series—are compared with regard to the mean TIAL and in many other ways, with illuminating results.

The book contains many tabulations and a great deal of statistical procedure. It is not an easy book to read in detail, but the general results are reasonably easy to comprehend. The chief results of the study are in part:

"The mean and median TIALS of the nonagenarians and centenarians are over 60 years, 16 per cent higher than those of the FHR series, indicating statistically the importance of ancestral longevity of the individual." Thus heredity is one important factor in longevity. The author recognizes other factors than heredity. He does not believe that longevity is inherited according to any known mendelian mechanism.

The study of the effects of moderate and excessive use of alcohol revealed the facts that 41.4 per cent of the longevous individuals were moderate drinkers, 4.1 per cent more than was found among the random sample of general population; that 3.7 per cent of the longevous males were heavy drinkers; and more than half (56.6 per cent) of the longevous individuals were total abstainers. In general, "the evidence from this study clearly indicates that the moderate use of alcoholic beverages throughout life is not incompatible with the attainment of great longevity."

This admirable piece of statistical work reveals nothing distinctly new or startling but puts on a sound basis much that had been believed to be true on the basis of casual observation and the study of isolated pedigrees.

Vital Cardiology: A New Outlook on the Prevention of Heart Failure. By Bruce Williamson, M.D., M.R.C.P., Physician Royal Northern Hospital, London. Cloth. Price, \$5. Pp. 344, with illustrations. Baltimore: William Wood & Company, 1934.

"The object of this treatise is to present clinical cardiology as a primary study of the two essentials which govern the cardiac output; namely, rate and force." With these words the author begins the preface. The opening chapters concern themselves with a discourse on the general ineffectiveness of modern medical practice and the fallacy of neglecting rate and force for murmurs and electrocardiograms in the study of heart disease. We are told (in italics) that "the heart has no intelligence"; that the new outlook on the prevention of heart failure should rest on the principle of "the prevention of involuntary wasteful living." The vagus and sympathetic nerves "are constantly on the watch for weakness in each other." The author's "apnea test" is said to distinguish "psychic tachycardia from all other types, whether physiological or pathological." On page 68 we read that "a mild degree of tachycardia is not an infrequent accompaniment of old age." On page 86 it is stated that "bradycardia is frequently met with in old age, especially in men." In part II are given discussions of various disturbances in rate and rhythm, of valvular defects and of the "myocardial potential." Part III concerns itself with symptoms, including precordial pain. Part IV deals with treatment.

In the therapy of coronary thrombosis, epinephrine is considered as a drug of great value, "given in 10 minim doses hypodermically four-hourly during the first few days, when the blood pressure is low, whether heart block is present or not." In the application of "preventive treatment" it is stated that "rate and force are the only factors which can possibly affect the efficiency of the heart and all other abnormalities must be interpreted in terms of their influence on these two essentials." Morphine may be safely used "in adults who still retain 60 per cent or more of active lung tissue estimated by auscultation; i. e., dry vesicular breathing is present in the major portion of the total lung field." Prolonged rest for young people after rheumatic endocarditis is believed to be "a definite factor in the high incidence of mitral stenosis we see today," for "stasis and stenosis are firm allies." "In cyanosis of purely cardiac origin, oxygen therapy is valueless." A half ounce of brandy or whisky in hot milk given at 2 a. m., when cerebral thrombosis has already occurred, "undoubtedly helps recovery and tends to prevent further thrombosis." "If the sole action of digitalis—and there is ample evidence in support of this—is stimulation of the vagus, which slows the heart, it follows that the sole indication for the use of this drug is tachycardia." According to this concept, other signs or symptoms of myocardial insufficiency are of no importance.

In the preface, the author predicts that "critics will find much material to discuss. A new view in medicine, to be worthy of discussion, must be based on adequate factual evidence. Dr. Williamson is quite evidently a physician with a considerable clinical experience. But in his book a majority of the ideas set forth, as well as the inferences drawn from the observation of patients, are unsupported by specific data. Only two references to the literature are cited in the entire work. In seeking advocates for such unorthodox views, it is essential to set forth fully the facts on which they are based. The volume, therefore, cannot be recommended, for the theories advanced are unproved, the deductions based on clinical observation are often fallacious and many of the principles of therapy outlined are, in the light of current knowledge, unsound.

Tratamientos de la intoxicación cianhídrica: Sus mecanismos fisiológicos. Por Enrique Hug, profesor de farmacología, Facultad de ciencias médicas, Rosario. Paper. Pp. 151. Buenos Aires: El Ateneo, 1934.

Professor Hug presents the results of his researches on cyanide poisoning carried out during the last four years. The tables and charts and most of the text have appeared previously in South American (Spanish) and French journals. An extensive review of the literature makes this a complete contribution. A work such as this has the advantage of presenting in collected form the important results and conclusions of an expert and authority. Hug includes a complete discussion of the work of North American authors. The first part discusses the toxicity of hydrocyanic acid and its salts and the mechanism of the poisoning. The second part takes up the antidotes according to the newer classification, namely, hyposulphite and colloidal sulphur, reducing sugars, methemoglobinizing substances, other antidotes and combined antidotes. Chapter VIII discusses results in man. The monograph ends up with general conclusions, a bibliography and an index. The author naturally devotes considerable space to a discussion of the methemoglobinizing agents. He must be credited with having recognized the great practical possibilities of methemoglobin formers in the treatment of cyanide poisoning. As a result of his studies, he introduced the use of sodium nitrite, which greatly exceeds in effectiveness all previously tried antidotes, including methylene blue. Hug was among the first to recognize that the antidotal actions of nitrite and methylene blue rest on a common basis, namely, on methemoglobin formation, which results in the formation of the nontoxic cyanmethemoglobin. He presents extensive chemical and pharmacologic data on the antidotal action of methemoglobin and admirably proves his case for it. As for the choice of an antidote in human cases of cyanide poisoning, Hug, like all other students of this subject, proceeds from experimental results on injected animals and cites cases successfully treated. Apparently he is not certain which antidote should be regarded as the best. He recognizes the value of methylene blue but is inclined to favor sodium nitrite, possibly combined with sodium thiosulphate. In South America the nitrite and thiosulphate have been tried successfully and safely. Probably most North

American physicians and pharmacologists would not yet be ready to adopt nitrite as the first choice, in view of the recent successes with methylene blue without attendant difficulties or serious consequences. It may be some time before the final choice of antidote is settled, as the present uncertainties lie on the clinical side and not on the experimental. Surely this monograph will prove valuable and profitable to all those handling cyanide and treating, or likely to treat, emergency cases of poisoning. No medical library, and no researcher who has failed to keep abreast of recent contributions on poisoning, can afford to be without a copy.

L'intoxication par les somnifères (Intoxication barbiturique). Par Charles Flandin, médecin de l'Hôpital Bichat, Jean Bernard, Interne des hôpitaux de Paris, et François Joly, Interne des hôpitaux de Paris. Paper. Price, 20 francs. Pp. 116, with 6 illustrations. Paris: G. Dolin & Cie, 1934.

Until recently, opiates were the favorite poisons for suicide; within the last decade, and most especially the last two or three years, barbiturates have taken first place. This, no doubt, is due to the fact that there are severe restrictions to the sale of opiates, while any one, anywhere, can obtain any quantity of poison of the barbituric acid series, enough to produce death. Until this condition is rectified by restrictive legislation, studies such as this are greatly needed. Flandin has had the opportunity of studying, in collaboration with two interns at the Bichat Hospital, sixty-two cases of this form of poisoning within the last eighteen months in one general medical service. This number of cases in a rather short span of time may serve to show the frequency of the occurrence of this condition as well as the relatively high degree of authority with which Flandin and his assistants speak on the subject.

This work is the most thorough presentation of barbiturate poisoning yet available, as may be gathered from the fact that it contains chapters on the chemistry and experimental physiopathology of the barbiturates, the methods of identification, the pathologic anatomy, the clinical etiology, the symptomatology, and the diagnosis, prognosis, treatment and prophylaxis, besides a bibliography covering more than twelve pages.

The prognosis, it is pointed out, cannot be based on the depth of the coma, because a complete coma is frequent in perfectly curable cases, while an agitated sleep may end in death. The presence of the corneal reflex is favorable, as is mydriasis, while miosis is unfavorable. The dose ingested and still more the time since it was taken before treatment is instituted are directly proportionate to unfavorableness of prognosis. The only true sign of improvement is recovery of consciousness. Even though the patient may again become unconscious, his recovery is imminent. While the reappearance of reflexes is a favorable sign, such reactions may be merely temporary in a grave case. While calm, regular respiration is favorable, irregular respiration is unfavorable. While the signs of pulmonary atelectasis do not modify the prognosis, those of secondary pulmonary complications, such as a pneumonia, greatly increase the gravity of the case. Enfeeblement of circulation is often absent: when it is present, the prognosis is grave. Anuria is part of the clinical picture of certain fatal forms. A normal secretion of urine is a favorable sign, provided it is well sustained. If the temperature does not exceed 104 F. and if it falls to normal within twenty-four hours, the case is likely to be favorable. If it exceeds 104 or is continuous, or if hypothermia prevails, death is likely to ensue. If the leukocyte formula is approximately normal, it constitutes an index of great gravity, no matter what the temperature. If, on the other hand, a leukocytosis appears in connection with a normal temperature or a temperature falling to the normal, it is likely to be a favorable omen. If the leukocytosis accompanies hyperthermia, it does not have the same favorable significance, provided it is possible to eliminate a visceral localization.

In the treatment, the principal factor is constant and unremitting care. Gastric lavage is, of course, essential if the patient is seen early; but, if the patient is first seen late, the indication for lavage may be disputable, as the poison is usually not found at that time in the stomach and lavage is not without danger of causing aspiration pneumonia. Abstraction of from 500 to 600 cc. of blood may be of some value, especially if followed by transfusion of from 500 to 800 cc. of blood, which if

repeated would secure a veritable washing of the blood. Dextrose saline solution should be administered continuously either by rectum or, in serious cases, intravenously. It is indeed the single most important therapeutic agent against barbiturate poisoning. The patient should be kept in the half sitting posture to prevent pulmonary complications. Oil is recommended for purgation. In case of heart failure, strophanthin (0.25 mg.) intravenously and camphor as well as epinephrine may be of use. But the most important antagonist is strychnine in enormous doses, even in doses exceeding the minimum fatal dose (0.03 Gm.) for normal individuals. In moderately severe cases, one should give intravenous injections of 0.01 Gm. of strychnine hourly; in very severe cases one should start with 0.05 Gm. (given very slowly) by intravenous injection and repeat this dose hourly or alternate the larger with the smaller dose hourly. The indications for letting up on the dosage of strychnine are either amelioration of the coma or signs of strychnine poisoning, indicated by the return of the reflexes, Chvostek's sign or more rarely by rigidity of the lower extremity. These come on rapidly, within two to ten minutes, often while the needle is still in the vein. The author accepts the theory of phylaxis, advanced by Billard, according to which strychnine, of value in preventing union of the depressant poison with the nerve centers, unfortunately is powerless to displace that which has become fixed in the nerve centers. If strychnine fails, one might try picrotoxin in doses of possibly 0.6 mg. given hypodermically. Coramine may be given in doses of from 3 to 10 cc. of the commercial solution in the twenty-four hours. Against respiratory depression, caffeine is the auxiliary remedy of choice. Inhalation of oxygen with the addition of carbon dioxide should be resorted to as soon as respiration seems to become insufficient, with artificial respiration reserved for final recourse if death seems imminent. It should be stated here that the safety and efficiency of these huge doses of strychnine advocated by the authors is by no means generally accepted or admitted.

The prevention of this form of poisoning must be accomplished by legal enactment by the addition of the barbiturates to the list of poisons covered by the antinarcotic law.

Die Haut- und Geschlechtskrankheiten: Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 17, Band V. Tripper der Mundschleimhaut, der Nase, der Ohren, des Mastdarms, des Auges, Allgemeinkrankheiten bei Tripper. Von Prof. Dr. Leo Hauck. Welcher Schanker (Ulcus molle). Von Prof. Dr. Otto Grütz. Lymphogranulomatosis inguinale. Von Prof. Dr. W. Frei. Venereisches Granulom. Von Prof. Dr. W. Frei. Paper. Price, 9.40 marks. Pp. 347-524, with 26 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

This portion of the fifth volume of this system of skin and venereal diseases is devoted in the first place to gonorrhea of the mouth, nose, ears, rectum, eyes, lymph channels, blood vessels, skin, heart, joints, muscles and tendons, discussed by Professor Hauck of Erlangen. Then soft chancre (ulcus molle) is considered by Professor Grütz of Wuppertal-Elberfeld. Thirdly, a venereal disease much in the limelight today, lymphogranuloma inguinale, is discussed from different angles by Professor Frei of Berlin, the deviser of the "Frei reaction," now so widely used in diagnosis and differential diagnosis of this disease. Professor Frei also devotes a few pages to granuloma inguinale. The physician desirous of a general survey of these diseases will find them, on the whole, clearly discussed in this small volume, at least, as far as gonorrhea, soft chancre and lymphogranuloma inguinale are concerned. Granuloma inguinale, on the other hand, is a rarity in Germany, and Professor Frei offers nothing new.

All the articles present a complete knowledge of the latest literature on the subjects, and while complete reference lists are not furnished, owing to lack of space, the reader is told where he can find them. The portions devoted to gonorrhea of the skin and mucous membranes, to soft chancre and to lymphogranuloma inguinale seem to be particularly well done. In handling the treatment of chancroidal bubo, the author has made no note of the injection treatment of the bubo; e. g., with Mercière's solution. Professor Frei feels more strongly than ever that inflammatory strictures of the rectum are due to lymphogranuloma inguinale.

The subvolume in boards is well printed, on excellent paper, and has twenty-four illustrations and two colored plates. All

of them are good except the representation of a case of granuloma inguinale. As is usual in most foreign books, there is no index, though the reader will find a tolerable division of the contents at the beginning of each section.

L'infarctus du myocarde: Etude expérimentale électrocardiographique et clinique. Par Eduardo Coelho, professeur à la Faculté de médecine. Lisbonne. Paper. Price, 35 francs. Pp. 212, with 103 illustrations. Paris: Masson & Cie, 1934.

Professor Coelho has produced a good monograph on the experimental, electrocardiographic and clinical aspects of myocardial infarction. Included in this work is a brief but excellent survey of the literature with a bibliography of 209 titles. He has presented animal experimental work of his own, consisting of ligation of the coronary vessels in the dog, and he also reports twenty-eight personal cases in medical practice. In summarizing the medical records of his patients Coelho has reported that twenty-seven showed the characteristic chest pain of coronary thrombosis. Only one failed to complain of pain and that one suffered from dyspnea instead. Twenty of the cases showed a considerable drop in arterial blood pressure, twenty-three a definite elevation in temperature, six a pericardial friction rub, and four acute pulmonary edema. Five of his twenty-eight patients died, three in the course of a second crisis of coronary thrombosis and two with acute pulmonary edema. The other twenty-three patients are "clinically cured," some for more than four and one-half years. Electrocardiographic study of these twenty-eight cases showed thirteen of the so-called T_1 type (probably indicative of thrombosis of the anterior descending branch of the left coronary artery with infarction near the apex of the left ventricle), ten of the T_2 type (with probable thrombosis of the right coronary artery and infarction at the base of the left ventricle posteriorly), two of both types, one with bundle branch block, and two with paroxysmal ventricular tachycardia (both these patients died). Two cases showed auriculoventricular block. The monograph ends rather abruptly without any discussion of treatment. It would be well worth while for the author to include a section on treatment and a further discussion on prognosis if a second edition is published.

Handbuch der inneren Medizin. Herausgegeben von G. v. Bergmann und R. Stachelin. Unter Mitwirkung von V. Sallé. Begründet von L. Mohr und R. Stachelin. Band I: Infektionskrankheiten. Bearbeitet von R. Doerr, A. Eckstein und anderen. Third edition. Cloth. Price, 96 marks. Pp. 1,299, with illustrations. Berlin: Julius Springer, 1934.

This is the first volume of the third edition of a system comprising the entire field of internal medicine. In accord with the custom prevailing, each chapter has been written by a different author who by his special inclination and research work seemed to be particularly competent to attend to the task allotted to him. In this way, following a general discussion of pathogenic micro-organisms and the reactions of the carriers, are in detail described all the infectious diseases occurring in human beings. While on account of financial conditions the volume of the preceding editions had to be cut down somewhat, this was not done at the expense of information offered but simply resulted in a more concise presentation. This publication takes first place as a text and reference book. The world's literature is extensively considered and properly indexed; 395 illustrations promote the understanding of the text.

The Operative Treatment of Collum Femoris Fractures. By Sven Johansson, M.D., Surgeon-in-Chief, "Allmänna och saligrenska sjukhuset." Göteborg, Sweden. Paper. Pp. 148, with 157 illustrations. Copenhagen: Levin & Munksgaards Forlag, 1934.

The author presents a method of treatment which he has found successful. Of a series of 3,635 patients admitted with a total of 3,940 fractures and dislocations, 390, or about 10 per cent, had fractures of the neck of the femur. Seventy-five per cent of the patients were over 60 years of age. The author quotes Radasch, who described the "medullary index": that is, the relation between the compacta and the bone marrow changes with increasing age, the medullary cavity growing wider while the cortex becomes thinner. He emphasizes the importance of taking roentgenograms, not only in the ventral-dorsal but also in the lateral projection. He advises an additional lateral roentgenogram of the unaffected hip. Johansson believes that interposition of tissue delays but does not necessarily prevent

complete osseous union. In his 390 cases there was a primary mortality of about 14 per cent. He states that the so-called Whitman method should be called the Whitman-Lorenz-Löfberg method, because each of the three worked the method out independently of the other two. He advises against inward rotation before one has obtained maximal abduction and extension. He believes in Cotton's artificial impaction.

Johansson's method is as follows: After carefully replacing the fracture he drills a fine, stiff, metal wire in the axis of the neck from a point slightly below the trochanter. After the position of the wire has been controlled both ventral-dorsally and laterally, it is used as a guide for the introduction of a metal nail of the same shape as that employed by Smith-Petersen but with the modification that it is provided with a central canal so that it can be threaded on the wire. No plaster cast is applied. The patient may be put in a Braun splint or with one sand bag on each side as support. After two weeks, active movements are begun cautiously and electrotherapy is instituted. The average confinement to bed has been thirty-one days. The average stay in the hospital was about eighty days. He has operated on about fifty patients and in only one did he fail to obtain satisfactory position and fixation by his method. He usually employs spinal anesthesia.

Medicolegal

Medical Practice Acts: Massage to Alleviate Pain as Constituting Treatment of Disease.—Thompson gave massages to two persons, one of whom had a pain in her shoulder and the other had a pain in the neck. He was convicted in the circuit court, Montgomery County, of treating diseases of human beings without a license. He appealed to the court of appeals, Alabama, where the judgment of conviction was reversed. *Thompson v. State*, 153 So. 469. The state then applied to the Supreme Court of Alabama for a writ of certiorari to review the decision of the court of appeals.

The medical practice act of Alabama provides, in part, as follows:

Any person who treats, or offers to treat diseases of human beings . . . without . . . a certificate of qualification from the state board of medical examiners, shall be guilty of a misdemeanor. . . .

In this case, said the Supreme Court, in order to warrant a conviction of Thompson, the state must show that he treated or offered to treat diseases of human beings. This the state failed to do. The term "disease," continued the court, means more than a mere temporary pain or disorder. In *Merriam v. Hamilton*, 64 Or. 476, 130 P. 406, cited and followed by the Alabama court, it was held that a complaint charging that the plaintiff had a backache was not sufficient as a charge that she had a disease, the court in that case observing:

True enough, the plaintiff says she had a backache, but pain is not a disease; it is only the symptom of some disorder of the body which in turn may not amount to disease or trauma.

To adopt the state's contention in the present case, said the court, would render any good Samaritan a lawbreaker who tried to ease or alleviate a pain by rubbing, or a bruise or temporary swelling or soreness with a poultice or hot water bottle. The record, in the opinion of the court, disclosed no violation of the medical practice act. The petition to review the decision of the court of appeals was therefore denied.—*Thompson v. State (Ala.)*, 153 So. 470.

Insanity: Irresistible Impulse and Criminal Responsibility.—Eatman was indicted for burglary. He pleaded that at the time of the commission of the alleged offense he was insane. At the close of all the evidence, the trial court instructed the jury to disregard all the testimony offered with reference to the insanity of Eatman. A conviction followed and Eatman appealed to the Supreme Court of Mississippi.

The sole question on appeal, said the Supreme Court, was whether the testimony relative to the insanity of the accused should have been submitted to the jury. Every lay witness except one was without doubt as to the sanity of the accused. Two witnesses testified concerning some peculiarities in the

conduct of the accused noted on isolated occasions, but, the court said, peculiarities of conduct on occasions do not amount to proof of insanity, else, in the judgment of many people, most of the people, other than themselves, would be insane. All the expert witnesses testified that the accused was a psychopathic delinquent without psychosis, that he had the capacity or ability to distinguish right and wrong but was deficient in inhibitory powers. The test of criminal responsibility, continued the court, is the ability of the accused, at the time he committed the act, to realize and appreciate the nature and quality thereof—his ability to distinguish right and wrong. The defense of irresistible or uncontrollable impulse is not available unless the uncontrollable impulse springs from a mental disease existing to such a degree as to overwhelm the reason, judgment and conscience. The reasons for the general rejection of the defense of uncontrollable impulse, in Mississippi, were set forth as follows in *Smith v. State*, 95 Miss. 786, 49 So. 945, 27 L. R. A. (N. S.) 461, Ann. Cas 1912A, 23:

It is known among medical writers as lesion of the will. Its peculiarity is said to be that, while the mental perception is unimpaired, the mind is powerless to control the will; that while its unhappy subject knows the right, and desires to pursue it, some mysterious and uncontrollable impulse compels him to commit the wrong. This kind of insanity, if insanity it can be called, though sometimes recognized by respectable courts, and still oftener, perhaps, by juries seeking an excuse to evade the stern dictates of the law, is properly rejected by the authorities generally. The possibility of the existence of such a mental condition is too doubtful, the theory is too problematical, and too incapable of a practical solution, to afford a safe basis of legal adjudication. It may serve as a meta-physical or psychological problem to interest and amuse the speculative philosopher, but it must be discarded by the jurist and the lawgiver in the practical affairs of life.

An expert witness in the present case testified that there was no practical or dependable way to tell whether the accused was in fact unable to resist the criminal impulses. The evidence, concluded the court, established the fact that the accused had the capacity to distinguish between right and wrong. The action of the trial court, therefore, in instructing the jury to disregard the testimony with reference to the insanity of the accused, was affirmed.—*Eatman v. State* (Miss.), 153 So. 381.

Workmen's Compensation Acts: Total and Permanent Disability Attributed to Traumatic Neurosis.—Duotwal was struck on the head by a 28-pound radiator, which fell several feet from its stacked position. Two fellow workers assisted him to the office of the company doctor, about 600 feet away. The company doctor treated a scalp wound and had the injured employee removed to a hospital. After the third day at the hospital, the scalp wound having healed, the injured workman was given permission to go home but he at first refused to leave the hospital. He acted and talked strangely, contending that he should stay at the hospital for at least two months because, as he said, he had no clothes. Later in the day, however, he did leave the hospital but owing to his nervous condition he was returned in about two weeks for a second stay of ten days. He complained of dizziness and headaches but otherwise appeared well nourished and not acutely ill. In a proceeding under the workmen's compensation act of Illinois, it was claimed on behalf of Duotwal that, following the blow on his head, a striking personality change took place. The injured employee, it was claimed, was rendered useless for remunerative employment; that the injury to his head had affected his mind, resulting in abnormal suspicion, distrust and hostility. Prior to the accident, the evidence showed, the employee had been a steady and reliable worker and had been regarded as jovial and optimistic. His family physician testified that his condition after the injury was distinctly different from his condition prior thereto. After the injury, according to the testimony of this physician, Duotwal was highly nervous and irritable and would become startled at any noise. He could not walk in a straight line, had a wild stare from bulging eyes, lacked coordination in speech, became discouraged and depressed, and had no interest in himself or his surroundings. An expert in mental diseases testified that Duotwal was a paranoiac and that he would get worse, not better, and that he could not carry on any work except simple tasks under supervision. Another expert witness testified that Duotwal was suffering from traumatic neurosis. An arbitrator of the industrial commission awarded compensation for total and permanent disability, which award was sustained, on review, first by the industrial com-

mission and subsequently by the circuit court of Cook county. The employers thereupon brought the case before the Supreme Court of Illinois for review.

The causal connection between the accident and Duotwal's incapacity for remunerative labor, said the Supreme Court, was established by the evidence. There was testimony showing that Duotwal was suffering from neurosis of traumatic origin which incapacitated him from doing anything of a remunerative nature. We have held, continued the court, that an employee is totally and permanently disabled when he is unable to make some contribution to industry sufficient to justify payment to him of wages. That there may be a later improvement in Duotwal's condition, said the court, does not defeat the award. If there is such improvement the employer has his remedy by appearing and asking for a modification of the award. The court thereupon affirmed the judgment of the circuit court in favor of the injured employee.—*Ford Motor Co. v. Industrial Commission* (Ill.), 189 N. E. 498.

Workmen's Compensation Acts: Refusal to Undergo Operation for Hernia.—An employee suffering from an operable hernia, said the Supreme Court of Oklahoma, must accept a tendered operation before he can claim compensation for total permanent disability. The employee may not, however, be compelled to take a risk of life, however slight, in order that the pecuniary obligation created by law against his employer may be minimized. This rule arises out of the high respect which the law has for human life. In the present case, the employee had worked for the United Service Street Car Company for fifteen years. During that time he had on two occasions, prior to the instant case, developed a hernia. The condition was corrected in each case by operation. On Jan. 27, 1933, the employee developed a third hernia from a strain. An operation tendered by the employer was performed but was unsuccessful. A second operation was offered, which the employee refused to undergo, basing his refusal on the advice of his physician that, owing to the presence of scar tissue in the vicinity of the hernia and other physical conditions, it would be practically impossible to perform a successful operation and that such an additional operation would be extremely dangerous. The state industrial commission awarded compensation for total and permanent disability, and the employer appealed to the Supreme Court of Oklahoma.

The burden of proving that the tendered operation was simple, safe and reasonably certain to effect a cure, said the Supreme Court, was on the employer. Where conflicting evidence is introduced concerning the safety of a tendered operation and the probability that a cure would be effected thereby, the reasonableness of the refusal of the injured employee to accept such operation resolves itself into a question of fact to be determined from the evidence. The evidence in the present case, as viewed by the Supreme Court, supported the finding of the industrial commission that the employee was permanently and totally disabled, that the tendered operation was useless and dangerous, and that therefore the employee's refusal to undergo the operation was reasonable. The award of the commission was consequently affirmed, with certain modifications.—*United Service Street Car Co. v. McCarter* (Okla.), 30 P. (2d) 456.

Society Proceedings

COMING MEETINGS

- American Society of Tropical Medicine, San Antonio, Texas, November 14-16. Dr. Henry E. Meleney, Vanderbilt University School of Medicine, Nashville, Tenn., Secretary.
- Pacific Coast Society of Obstetrics and Gynecology, Oakland and Del Monte, Calif., November 21-23. Dr. Clarence A. De Puy, 230 Grand Avenue, Oakland, Secretary.
- Puerto Rico, Medical Association of, Santurce, Dec. 14-16. Dr. Julio R. Rolenson, Box 3403, Santurce, Secretary.
- Radiological Society of North America, Memphis, Tenn., December 3-7. Dr. Donald S. Childs, 607 Medical Arts Building, Syracuse, N. Y., Secretary.
- Southern Medical Association, San Antonio, Texas, November 13-16. Mr. C. P. Loran, Empire Building, Birmingham, Ala., Secretary.
- Southern Surgical Association, Sea Island, Ga., Dec. 11-13. Dr. Robert L. Payne, 142 York Street, Norfolk, Va., Secretary.
- Western Surgical Association, St. Louis, December 7-8. Dr. Albert H. Montgomery, 122 South Michigan Boulevard, Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Metabolic and Nutritional Aspects of Chronic Arthritis.—Pemberton stresses the importance of a restricted but balanced diet in arthritis, with the curtailment of that fraction which affords most of the calories in the ordinary American diet: the carbohydrates. A diet of this nature, while valuable in a restricted sense to all arthritic patients, can have intensive application only to those cases that have been found on study to be suitable for it. In many sufferers from arthritis and in a great majority of all advanced cases, the gastro-intestinal tract presents certain dysfunctions and anatomic configurations. The most obvious evidences of this are atony, enteroptosis, often masked stasis, dilatation and elongation of the large intestine and frequently hypochlorhydria. This picture is, of course, not pathognomonic for arthritis. Under suitable dietetic control the

gastro-intestinal tract so dysfunctioning and deformed may be made to approach or even reach a picture of normality, more or less coincidentally with the restoration of health in general. Fletcher believes that an unappreciated vitamin deficiency plays a determining part in this sequence of events in arthritis. In suitable cases restoration toward normal with relief from the arthritis will follow short periods of low calory feeding from which all vitamins are excluded definitely. A diet relatively low in carbohydrate and relatively high in protein has, as a necessary physiologic consequence, a depletion of the water reserves of the body and under this influence the edema can be observed to disappear. For every drachm of carbohydrate stored 3.6 Gm. of water is retained, and an obvious therapeutic corollary to this is the avoidance of such storage and of such water retention. This subsidence of swelling to be observed under these conditions is accompanied by a constant loss of weight and the establishment of a negative water balance and usually by clear-cut diminution of pain. The several major systems of the body are intimately interdependent one on the other. Conditions that tend to restore gravitational and other equilibrium in the vascular system, meaning chiefly the finer distribution of it, promote subsidence of the excess tissue fluids. At least part of the stiffness and pain experienced in arthritis is referable to excess fluids confined within the limiting membranes of various types of structures, such as the tendon sheaths. Other tissues, and even cellular units, could be expected to be affected comparably. These observations emphasize that arthritis is a systemic disease and that only a wide-angled outlook on it can hope to have successful consequences in the treatment of any considerable number of sufferers from it. A coordination of several lines of therapy, based on sound physiologic premises, should control definitely the disease in about 80 per cent of all cases.

Diabetes Mellitus.—Boldyreff states that, if the small pancreatic duct is ligated in a dog and the large duct is used for a fistula, all the pancreatic juice will flow outside (this operation is functionally identical to a complete pancreatectomy, although much easier of execution). In twenty-four hours this dog becomes diabetic, although his so-called internal pancreatic secretion is as before. Such dogs develop not only glycosuria and azoturia but also lipemia (the carbohydrate, fat and protein metabolism is affected). All the diabetic symptoms are present in a severe degree in such dogs. If the ligature from the small pancreatic duct is removed, severe diabetic symptoms decrease at once. But if the fistula of the larger pancreatic duct is closed the animal gradually recovers completely. Therefore, removal from the animal or human body of the external pancreatic secretion leads to diabetes. Hence the direct conclusion to treat diabetes by introduction of pancreatic juice. When administered by mouth, both digestion and metabolism are improved. Diabetes is a disease of the digestive organs (mainly of the pancreas) and therefore diabetic patients should have their digestion in proper order. First of all, the digestive work should be minimized; then anything capable of hindering digestion or irritating digestive organs should be avoided. The effect of insulin is not direct, but it is actually accomplished through the secretion of the gastric, pancreatic and intestinal juices caused by insulin. Since insulin is toxic and its effect is fleeting, a more suitable and rational medicine should be found. As such a medicine, the pancreatic juice is recommended, in which case, imitating nature, diabetic patients should be treated by introduction of the natural pancreatic juice into the duodenum.

Aluminum Hydroxide in Treatment of Peptic Ulcer.—Einsel and his associates observed that in the treatment of ulcer with aluminum hydroxide a large proportion of patients became symptom free in from two to seven days, even if they had had a recurrence lasting for several months. The 110 patients were treated from one month or less to three years. There were nine patients in whom symptoms remained or who had recurrences. The failures were due to the fact that the patients would follow no diet because of not having the food or because they would not cooperate. The patients were put on a modified Sippy convalescent diet, consisting of six feedings a day, followed by from 1 to 3 drachms (4 to 12 cc.) of gelatinous aluminum hydroxide from half an hour to one hour

after the ingestion of food. Constipation was controlled by agar and liquid petrolatum. Phenolphthalein was added when necessary. The patients after the first two or three weeks were allowed to work if the work was not too strenuous. They were cooperative because they did not have so many things to do in following the directions of the treatment. The free acidity of the stomach is lowered after treatment with aluminum hydroxide but returns to the initial level after the medication is discontinued. Although aluminum hydroxide serves obviously as a gastric antacid, it is possible that its efficacy in the treatment of peptic ulcer may be dependent in part at least on its slight astringent and demulcent properties and the fact that it appears to increase the secretion of mucin. No contraindications for aluminum hydroxide therapy have been observed. Determinations of the total base, chloride, carbon dioxide content and p_n of the blood failed to disclose any disturbance in the acid-base balance that could be ascribed to this therapy.

Convalescent Serum in Treatment of Poliomyelitis.—

In determining the value of convalescent serum in preparalytic poliomyelitis, Fischer observed that the outcome for the treated patients was no better than that for the untreated ones, if as good; while the controls were probably somewhat milder, he feels that no advantage was shown by the other group of 579 patients with poliomyelitis seen early in the course of the disease, of whom 477 were treated by injection of convalescent serum. A sufficient number of control cases should be obtained, as the author's present study has demonstrated that there is no proof that a physician is depriving his patient of an equal chance for complete recovery by not administering convalescent serum. Lacking a substitute therapeutic procedure, it would seem fair in subsequent epidemics to retest the value of potent serum in the preparalytic or meningitic stage of poliomyelitis, using, if possible, exactly parallel or alternate cases for control.

Cerebral Injury in the New-Born.—Shannon states that the syndrome consisting of tetany, generalized edema and edema of the brain in the new-born infant occurs as a result of some interference with the calcium metabolism which results in a lowered ionic calcium content of the blood and tissues. The possible causes of this deficiency in ionic calcium are the same as those that might be responsible at any age—excess of sodium or potassium, calcium starvation, parathyroid deficiency and alkalosis—and they may and probably do work in combination in bringing on the symptoms. Since the syndrome is constitutional, it follows that the symptoms commonly attributed to cerebral injury and to atelectasis may be of constitutional origin. Therefore the problems of cerebral involvement and of atelectasis and related conditions must be viewed from a more comprehensive angle than merely from that of the obstetric procedure, a factor that in the long run is probably less important than the other elements. Calcium therapy is specific for the syndrome. This is as true for the serious symptoms of cerebral edema as for the less serious ones of tetany and generalized edema. Since the symptoms of cerebral edema from calcium deficiency are indistinguishable from those commonly attributed to cerebral injury from other causes and are often indistinguishable from those usually credited to atelectasis, it follows logically that the hypothesis offers an extremely valuable additional method of therapeutic approach in such cases.

Giant Excavation and Emphysematous Bulla Mistaken for Pneumothorax.—Karan and Haymaker report two cases in which a mistaken diagnosis of pneumothorax was made: one a case of tuberculous vomica occupying almost an entire lung, the other a case of an immense emphysematous bulla. In both instances necropsy was performed. In the first case physical examination was of little aid in arriving at a correct diagnosis. It tended to confirm the presence of pneumothorax suggested by the roentgenogram. Iodized poppy-seed oil instillation might have been of value, for it would have shown the defects in the bronchial tree and would have collected entirely on the floor of the excavation. On the other hand, if the pathologic picture had been that of a tuberculous pneumothorax with bronchopleural fistula, the iodized oil would have passed through the fistula and settled on the floor of the pneumothorax cavity. The patient was too ill for bronchoscopic examination. Aspiration would have been of value if the condition had been that of closed pneumothorax. However, it could not have differentiated a giant cavity from a pneumothorax with bronchopleural fistula. The patient had no hemoptysis or even blood-tinged sputum throughout the course of the disease. In the second case, bronchoscopy with iodized poppy-seed oil instillation would have been of diagnostic value for the reason that a bronchial tree could have been demonstrated within the wall of the emphysematous sac. A view of the roentgenogram in retrospect does cast some doubt on the diagnosis, because there is no distinct demarcation between the area of decreased density and the pulmonary tissue. If the diagnosis had been doubted, roentgenograms taken in lateral and oblique positions might have been of diagnostic value. Bronchoscopy and instillation of the iodized oil should be used as a routine measure in doubtful cases of pneumothorax.

Atypical Perthes' Disease.—Freund presents a case of atypical Perthes' disease in which a distinct line of fracture in the subchondral zone was visible in the first roentgen studies of the hip joint. The patient was decisive about his trauma. The mechanism of the trauma is not clear but the author believes that a compression fracture occurred bringing about an aseptic necrosis of the bone. Not the entire femoral epiphysis was involved as is usually true in a definite case of Perthes' disease. Only the central portion of the epiphysis that lies just below the outer edge of the acetabulum was affected by aseptic necrosis. The compression fracture of the central portion of the epiphysis led to a decrease of the central portion of the head and a slight increase of the roentgen shadow. The roentgenologic changes of the hip joint (especially of the femoral head) are not pathologic by themselves, they are rather an expression of a reorganization; i. e., a healing process going on in the necrotic areas and sustained by the healthy tissue. The central portion, which was not yet invaded by the reorganizing fibrous bone marrow, assumed

more and more the wedge-shaped appearance of the sequestrum. An increased shadow, cast by the central portion, was due to the comparatively atrophic nature of the surrounding parts together with a filling out or plugging up of the marrow spaces by small bone fragments and bone detritus, which arose at the site of fracture. The fracture line itself disappeared rather early. This should not be interpreted as a complete healing of the fracture, because it is impossible for bony callus to be produced in the necrotic zone. Roentgenologically, the joint cartilage seemed as in the cases of Perthes' disease—uninvolved. The earlier roentgenograms showed even a widening of the joint space as compared with that of the normal side. The joint space itself showed more pronounced changes than are seen in the average case of Perthes' disease. The swelling of the hip region, the tenderness, the marked limitation of motion and the increase of temperature pointed to an infectious process, and drainage was considered. Two tuberculin tests were negative. In the early roentgenograms no changes in the epiphyseal plates or in the juxta-epiphyseal portion of the neck could be seen. There were no signs of a circumscribed or a diffuse osteoporosis. Later it did seem that the apex of the wedge-shaped area crossed the epiphyseal plate and reached the juxta-epiphyseal portion of the neck. This portion became resorbed quickly, but there followed disintegration of the epiphyseal plate between the head and neck and also of the epiphyseal plate of the greater trochanter. The disintegration of these plates led to a shortening of the limb of more than $1\frac{1}{2}$ inches. The osteoporosis alone suggested to the author that he was not dealing with a necrotic bone area undergoing dissection but rather with one that was previously necrotic and subsequently replaced by new bone tissue. For some reason, it has not yet become homogeneously fused with the surrounding cancellous bone.

- Importance of Social Diagnosis in Treatment of Tuberculosis. Beulah Burhoe.—p. 514.

Regulation of Intra-Abdominal Pressure.—Salkin points out that there exists in the abdominal wall a process of adaptability which attempts to change intra-abdominal pressure. This process may be called "abdominal accommodation" and is of a high degree of efficiency. Abdominal accommodation is dependent on an intact neuromuscular system and may be regarded as a reflex mechanism in the conservation of the activity of the body. This mechanism has a direct clinical bearing on intra-peritoneal procedures and the functional coordination of pleural and peritoneal cavities. Such factors as posture, intra-abdominal fossae and visceral displacement are of secondary and negligible importance in accommodation. The muscle contributes its elasticity and the nervous system makes possible the activity and the changes in the tone of the process. Combined, they produce an adaptability of the abdomen to adjust itself to any condition that may change its optimal pressure.

Comparison of Old Tuberculin with Tuberculin Protein.—Barnwell and Pollard state that Seibert's tuberculin protein (T. P. T.) can be incorporated in dry powder in minute amounts (0.001 mg.) in tablets of dry lactose, with an accuracy comparable to that obtained by the dilution of old tuberculin by quantitative chemical methods. The lactose alone produces

no reaction in tuberculous patients. Among those reacting to either T. P. T. or old tuberculin, the proportion of severe and mild reactions is about the same when roughly comparable protein doses are used. Seibert's tuberculin protein, 0.0001 mg., is equivalent in potency to 0.1 cc. of 1:10,000 old tuberculin in terms of percentage reactions among students. Every student reacting to 0.0001 mg. of T. P. T. reacted to old tuberculin in some dilution up to 1:100. Every patient with proved tuberculosis (about 100), including skin tuberculosis, reacted to some dose of T. P. T. up to 1 mg. As the doses of old tuberculin and T. P. T. are increased in multiples of 10, many more students react to T. P. T. than to old tuberculin. Twelve persons who reacted to T. P. T. and not to old tuberculin presented evidence of previous tuberculous infection in the roentgenograms. One with such evidence gave a reaction to old tuberculin but not to T. P. T., and seven were negative to both tuberculins (T. P. T. 0.01 mg. and old tuberculin 1:100). The authors present evidence to show that sensitization does not account for the differences in the number of reactions between old tuberculin and T. P. T. They suggest that the comparison of the proportion of reactors in simultaneous tests on apparently healthy persons is a delicate method of standardization of an unknown against a known tuberculin. Seibert's tuberculin protein in the doses used suggests that tuberculinization in the authors' community is at a higher level than that indicated by old tuberculin 1:100.

Peripheral Vascular Disease.—Landis maintains that in peripheral vascular disease, if the surface temperature fails to reach the normal level in a room at suitable temperature it can be concluded that the arteries supplying the part are unable to dilate owing to organic changes in their walls. The author induces vasodilatation of the peripheral vessels by immersing two extremities in warm water, verifying abnormal observations in most instances by anesthetizing the posterior tibial nerve. Patients with coldness, blueness or pain in the lower extremities who under suitable conditions show a normal elevation of skin temperature, 31.5 C. (88.7 F.) or more, are free from significant organic arterial obstruction. When the temperature of the skin fails to reach 31.5 C. but reaches 26 C.

(78.8 F.) or more, only a moderate grade of organic occlusion is present. In such patients benefit can be expected from contrast baths, local heat, diathermy, vasodilator drugs, the warm cradle or sympathetic ganglionectomy, all of which increase blood flow by dilating those vessels which are still capable of expansion. In the presence of rigid arteries incapable of dilatation, the total fall in pressure in the peripheral vascular system may be increased by elevating systemic blood pressure or by diminishing venous pressure. The author employed alternate periods of suction and pressure in sixteen patients with advanced peripheral vascular disease with the aid of an aluminum box large enough to accommodate the lower extremity to a point 6 inches above the knee where the thigh was surrounded by an air-tight rubber cuff. An air pump, valve, mercury manometer and relay were so arranged that the lower extremity was exposed alternately and automatically to a negative pressure of from 80 to 120 mm. of mercury for twenty-five seconds and a positive pressure of from 60 to 80 mm. of mercury for five seconds. In each instance the disease was of long standing; the patients suffered from thrombo-angiitis obliterans, simple arteriosclerosis or diabetes with arteriosclerosis. Eventually amputation was performed in all four patients with frank gangrene. Patients with indolent or slowly enlarging ulcers, but without frank gangrene, large sloughs or extending necrosis, often obtained striking relief from rest pain. Sleep ordinarily became possible without sedatives after a few days. The results in patients with intermittent claudication have been less striking, though in general slow improvement was observed. Alternate suction and pressure increase blood flow temporarily, even after organic vascular disease has diminished or abolished vasodilatation. Contraindications to the use of suction and pressure can be given. Active or acute infection may be influenced unfavorably by the procedure. Osteomyelitis, however slight, makes it unlikely that complete healing of cutaneous lesions can be obtained as long as drainage from beneath continues. When large masses of tissue are actually gangrenous or sloughing, only temporary relief has been observed so far.

Hypoglycemia in Diabetes and Obstruction of Pancreatic Duct.—Zeckwer discusses an unusual case of hypoglycemia. The patient had a history of diabetes but had been unwilling to cooperate and had not received insulin. He came to the hospital moribund and in a state of hypoglycemia. He had been eating little for a week before admission. Intravenous administrations of dextrose promptly brought him out of coma and mental confusion, but he relapsed several times into hypoglycemic shock. Necropsy revealed that pancreatic calculi and calcification had caused almost complete atrophy of the acinar and island cells of the pancreas. This amazing atrophy is the closest possible clinical parallel to experimental pancreatectomy in dogs. No pancreatic juice was available to this patient. The liver showed degenerative changes microscopically. The factor of undernutrition must be considered in the production of the hypoglycemia in this case but has less experimental basis than the effect of loss of external pancreatic secretions. In 10,300 necropsies, only four other instances of pancreatic calculi could

be found, none of which were associated with diabetes. The author suggests that when the liver is damaged through loss of the external secretions of the pancreas, especially if the condition is aggravated by undernutrition and tuberculosis, hypoglycemia may result in diabetes even in the absence of treatment with insulin.

Essential Fructosuria.—Silver and Reiner report three cases with metabolic studies of two and state that essential alimentary fructosuria is a specific, probably inborn, error of metabolism, characterized by the inability of the organism to utilize fructose normally and manifested clinically by a symptomless excretion of fructose. Fructose is passed in the urine only if fructose or substances capable of yielding it on digestion are ingested. All the reducing substances disappear from the urine if these foods are removed from the diet. The usual sources of fructose are cane sugar, honey and fruit. This disorder is not inconsistent with longevity and there is no reason to believe that it is a precursor of a diabetic state. Transition from fructosuria to glycosuria has never been observed. The tolerance and metabolism of all the other known carbohydrates are normal in this condition. Dextrose, taken orally by the patient whom the authors studied, gave only the expected rise in blood sugar and caused no glycosuria, and the hyperglycemia reached the fasting level by the fourth hour. Galactose was tolerated in a normal dose of 40 Gm. The relative insignificance of insulin and epinephrine in the metabolism of fructose compared with dextrose is pointed out and the possible intermediary metabolism of sorbitol is discussed.

Chronic Manganese Poisoning.—Canavan and her associates report the case of a man, aged 69, with manganese poisoning, evidenced by stiffness in the legs and gait, frequent falls, fatigability and sleepiness, who died of cardiorenal disease fourteen years after the onset of the symptoms due to the occupational hazard. The brain showed atrophy over the vertex and lateral aspects but not at its base. This atrophy was somewhat more pronounced than that usually present at that age. On frontal section the atrophy was conspicuous, and there was dilatation of the lateral ventricles with marked shrinking of the basal ganglions. Microscopic examination showed some diffuse cellular changes in the cerebral cortex and cerebellum, but the significant pathologic process was found in the basal ganglions, in which degeneration of nerve cells, satellitosis and gliosis were found. There was little difference of intensity in the process between the caudate nucleus, the putamen, the globus pallidus and the thalamus; in amount of gliosis, the optic thalamus led slightly, but marked focal scars were seen in the caudate nucleus and in the globus pallidus. The effect of the cellular damage noted in small sections was strikingly shown by the large total sections of the brain stained by the Weigert myelin sheath method. In those sections the shrinkage of the basal ganglions was measurable, distorting the anatomic outlines.

Atopy as Cause of Epilepsy.—Forman discusses five cases of epilepsy, which heretofore have been indistinguishable from other cases of essential or idiopathic epilepsy, occurring in persons with an inherited tendency to specific, abnormal reactions to certain inhalants, contactants and foodstuffs; that is, atopy. Since almost every other possible theory has been evoked to explain epilepsy, it is to be expected that the seizures would suggest a hypersensitiveness. Enough evidence has been brought forward to show that atopic phenomena are present in

a small proportion of epilepsy cases. Atopy can be only one of many causes of epilepsy. The essential criteria for the recognition of atopy are: (1) a familial and (2) a personal history of asthma, hay fever, vasomotor rhinitis, hives, eczema, migraine-like headaches and other allied conditions, (3) eosinophilia in the blood preceding and during the attacks and (4) positive reactions to cutaneous tests for sensitiveness to protein. If a family history of atopic manifestations or a personal history revealing other atopic reactions in the patient himself is not obtained, the patient is returned to the neurologist. But if such a history is obtained, the remaining criteria of eosinophilia and positive cutaneous reactions are sought. With these rigid requirements one may eliminate the instances (at least 25 per cent) of atopic persons whose family histories are negative for allergic manifestations and of patients who do not give positive cutaneous reactions. Later, when the thesis of this paper has been established, the allergist may assume the less rigid requirements demanded for pollen hay fever. Skin tests and clinical trial are the two methods of identifying the offending substances in atopy.

Phytotoxic Index in Schizophrenic Patients.—Freeman and Looney studied the inhibitory effects of 1 and 2 per cent solutions of defibrinated whole blood in a 50 per cent solution of nutrient Shive solutions on the growth of the roots of *Lupinus albus* seedlings. Male schizophrenic patients and normal male subjects, all free from any perceptible organic diseases, were used. A modification of Macht's original procedure was employed. No significant differences were found in the inhibitory action of whole blood in strengths of either 1 or 2 per cent between male schizophrenic patients and the normal male controls. Likewise no abnormal inhibitory action on the growth of these seedlings was demonstrable by using a 2 per cent solution of diluted urine. No inhibitory action was obtained with toluene in solutions four times as strong as that which had been used as a preservative. No existing correlation was found with the phytotoxic indexes of the solutions of blood or urine of the patients and their age, period of hospitalization or subtype of schizophrenia.

Ocular Lesions from Thallium Acetate Poisoning.—The experiments of Swab indicate that thallium acetate is fatal to experimental animals when administered even in small doses. Rodents exhibited greater tolerance to the drug than dogs. Feeding experiments with rats failed to cause cataractous changes that could be detected even histologically. All experimental animals presented evidences of pathologic change in every part of the visual pathway, even including the cortex of the occipital lobe. The lens was the only structure of the eyeball that was not affected by the intoxication. Massive round cell infiltration was frequently encountered in the ciliary body as well as in the retrobulbar connective and muscle tissues.

Myocardial Changes in Hypertension.—Levine made gross and microscopic examinations of twenty-seven hypertensive hearts. For the microscopic examination, blocks of tissue were taken from seven different locations in each heart. Six hearts were found to have marked sclerosis of the large coronary arteries and six had a marked sclerosis of the arterioles in one or more sections. Since one of the six with marked arteriosclerosis also had marked sclerosis of the large coronary arteries, there were eleven hearts that had marked organic changes in the arterial tree. The remaining sixteen hearts had changes in the arterial tree that were considered too slight to have seriously interfered with the supply of blood. In all the hearts, minute myocardial scars were observed in many areas. The most marked scarring was present in the hearts with marked alteration of the wall of the arteries and arterioles, but many hearts without organic arterial changes had marked interstitial fibrosis. No correlation could be found between age, sex, race, weight of the heart, blood pressure, the cause of death or the presence of syphilis and the amount of myocardial fibrosis. Many of the scars in the myocardium were observed to contain varying amounts of elastic tissue. This confirms the contention of Perkins and Miller that stress and strain can convert collagenic connective tissue into elastic tissue. Endocardial sclerosis was present in all the hearts, being as a rule most marked in the left auricle. It was due usually to an increase in smooth muscle cells and elastic fibers. In the sixteen hearts without organic changes in the arterial tree the functional changes undoubtedly acted over a long period and in a mild degree, leading only to myocardial fibrosis.

Bilateral Glioblastoma Multiforme.—Taylor reports two cases of bilateral glioblastoma multiforme. In the first case, tumors of the left temporal and right parietal lobes were found joined by a filamentous strand of tumor tissue. This passed from one hemisphere to the other just posterior to the splenium of the corpus callosum. It was thought that the left temporal tumor was primary and produced a similar lesion in the right parietal cortex by direct extension into the opposite hemisphere. In the other case the tumor was believed to be a bilateral glioblastoma multiforme of the frontal lobe of multicentric origin. No communication or extensions could be demonstrated. The possibility of metastasis from one frontal lobe to the other could not be ruled out entirely, since the pia-arachnoid bounded a small portion of each growth. There was, however, no other suggestion of metastasis in the brain.

Obliteration of Hemorrhoids with Negative Galvanism.—Keesey believes that 90 per cent of all hemorrhoids are amenable to negative galvanic treatment. Although surgical treatment is the only method for external hemorrhoids, all cases of internal and most cases of mixed hemorrhoids can be obliterated permanently and safely with negative galvanism. The superiority of negative galvanism for internal and mixed hemorrhoids is based on simplicity of technic, safety of procedure and permanence of cure. Equipment embraces a generator that provides a smooth galvanic current and needle electrodes susceptible of flexible manipulation. A needle guide-holder eliminates the need of assistance. The advantages of negative galvanism, he says, far outweigh its minor inconveniences, chief of which is the time involved for each of a series of successful applications.

Diabetes Mellitus and Hyperthyroidism.—Hills and his associates report a case that presented the symptoms of mild diabetes and mild hyperthyroidism. The patient had had diabetes during the three previous years. The hyperthyroidism had come on apparently two months before. Twenty-four hours after the patient knew that she was to be operated on, hyperglycemia and ketonuria developed in spite of precisely the same regimen that had controlled the diabetes during the eight preceding months. Extreme fear had apparently precipitated an exacerbation of the hyperthyroidism, and this in turn had caused a decrease of sugar tolerance. After six days of preoperative treatment, marked hyperglycemia persisted. A subtotal thyroidectomy was performed. Following the operation, sugar tolerance was markedly decreased, necessitating the daily administration of from 200 to 890 units of insulin. Compound solution of iodine given for four days was without benefit. Irradiating the pituitary was considered, but a roentgenogram showed that the sella turcica was smooth in outline and only slightly larger than normal. The onset of bronchopneumonia and a urinary tract infection produced a marked ketosis, which necessitated 890 units of insulin in twenty-four hours. The intravenous injection of sodium bicarbonate brought about a subsidence of the acidosis. The sugar tolerance increased

rapidly following the resolution of the pneumonia. However, vascular collapse and repeated insulin shocks were followed by cerebral thrombosis with hemiplegia and aphasia. After this, the patient improved gradually. Contrary to the experience of John, Joslin and Lahey, who point out that thyroidectomy lowers total metabolism and consequently improves the carbohydrate tolerance, the patient showed no improvement. She was refractory to insulin before the removal of her thyroid, but not until after the emotional disturbance precipitated by her decision to undergo thyroidectomy. When she left the hospital, twice as much insulin was required to control the diabetes as had been necessary before the thyroidectomy. The cause of the ineffectiveness of insulin was not determined.

Viosterol for Hay Fever and Asthma.—Rappaport and his collaborators observed 212 patients suffering from seasonal hay fever and asthma. Of these, sixty-eight were treated with viosterol 10,000 X and 144 were treated with viosterol and pollen injections. Of the first group, 82.4 per cent experienced definite relief; 96.5 per cent of the second group had comparable degrees of relief. The combined treatment of viosterol and pollen injections is more effective than either one alone. The nature of the protective action of viosterol is as yet undetermined. It does not seem to be related to the calcium mobilizing power of viosterol. The optimal dose of 10,000 X viosterol along with pollen injection for pollen sensitivity is between 2 and 10 drops (0.12 and 0.66 cc.) daily, varying with the susceptibility of the patient rather than with the severity of the symptoms.

Sedimentation Rate in Hay Fever.—The study of Gelfand and Victor of sixty-three hay fever subjects revealed that only one showed a slow sedimentation rate. Of forty-two hay fever subjects observed before and during the season there were twenty-nine with normal rates. These had no disease complication whatever, in contradiction to the observations by Schulhof, who expressed the belief that a normal sedimentation rate in allergic persons is indicative of the presence of a more or less serious pathologic complication. There were twelve patients showing increased sedimentation rates, five of whom presented serious disease complications. The remainder had physiologic complicating conditions, such as pregnancy or menstruation. Only two of the sixty-one hay fever subjects investigated gave a slow sedimentation rate. The results of the authors' study seem to agree with those of Westcott and Spain in finding that a normal sedimentation rate is the rule in hay fever. The authors state that the rate remains normal during the hay fever season and that treatment with pollen extracts produces no effect. Therefore they believe that the sedimentation rate is of no diagnostic value in hay fever subjects and cannot be used as a test, for instance, to determine alteration, either a rise or fall, of the immunologic state of the hay fever patient.

Ingestion of Staphylococcus Exotoxin.—Dolman obtained bacteria-free filtrates containing staphylococcus exotoxin of specific pathogenic and antigenic properties from about 200 strains of staphylococci. Forty-two volunteers drank staphylococcus filtrates with impunity on 110 occasions, most of the filtrates containing highly potent exotoxin. One strain yielded a filtrate of which 2 cc. caused severe gastro-intestinal disturbance in three of nine volunteers and a lesser degree of disturbance in four others. Although under certain conditions a staphylococcus metabolite is produced which causes symptoms of gastro-enteritis in human beings, only occasional strains are able to produce this substance, the identity of which is distinct from the exotoxin. The actual incidence of staphylococcus food poisoning is therefore not likely to be high.

Bacteriophage in Bacillary Dysentery.—Feemster discusses the laboratory observations of an epidemic of 109 cases of ileocolitis, in which the Hiss-Y dysentery bacillus appears to have been the principal etiologic factor. The Hiss-Y dysen-

tery bacillus was isolated from only 5.6 per cent of the stools collected from sick patients. Bacteriophage for the Hiss-Y dysentery bacillus was found in 80 per cent of the stools taken during the second week after the onset and in 45 per cent of those collected during the third week. The longest time after the onset in which bacteriophage was demonstrable was sixty-three days. None was found in the stools of a control group who had not been ill or in specimens obtained six months after the attack from patients who had recovered. Detection in the stool of a bacteriophage active against the bacillus causing an outbreak of dysentery seems to be a supplemental and valuable procedure for determining the etiology of cases of diarrhea.

Streptococci That Resemble Diphtheroids in Subacute Endocarditis.—Ferguson and his co-workers describe two cases of subacute bacterial endocarditis in which diphtheroid appearing organisms were recovered repeatedly from blood cultures during life. In one case, Gram-Weigert stained sections from a vegetation on the aortic valve at necropsy showed both diphtheroid appearing forms and chains of streptococci in each section. Bacteriologic investigation in both cases showed that the streptococcus under study existed in two phases, a typical streptococcus phase and a diphtheroid phase. The organism isolated from blood cultures in the diphtheroid phase changed under suitable conditions into a green producing streptococcus, which is unquestionably of etiologic significance.

Chronic Hypoglycemia in Childhood.—Kramer and his associates describe two cases of persistent chronic postabsorptive hypoglycemia in children. The first case presented a condition that is probably familial. The enlarged liver showed no glycogen but extensive fatty infiltration. There was sufficient hepatic tissue to perform its metabolic functions except that of glycogenesis. This primary failure to form glycogen from dextrose and the consequent absence of deposits of glycogen in the liver resulted in its secondary inability to mobilize the dextrose and maintain a normal blood sugar level. The authors advance a hypothesis for the presence of the fatty infiltration; e. g., the conversion of the dextrose into fat since the dextrose could not be transformed into glycogen. The nature of the hypoglycemia of the second child is still not known definitely. An associated organic condition of the central nervous system has raised the question as to whether this lesion is not respon-

sible for the hyperinsulinism rather than that the authors are dealing with a purely pancreatic hyperinsulinism due to neoplasia or hypertrophy and hyperplasia of the islands of Langerhans. They feel that, since up till now no definite case of hypoglycemia has been described due to a lesion of the central nervous system and since, on the other hand, there are a sufficient number of unquestionable cases of hyperinsulinism due to a pancreatic lesion, they are probably dealing with pancreatic hyperinsulinism and that the changes of the central nervous system are either secondary or independent of the primary condition.

Lateral Sinus Thrombosis.—Wible and Slotkin present a case, in a child of 6 years, that illustrates the problem of a masked sinus thrombosis in the presence of a complicating pneumonitis. When surgical intervention was finally resorted to, the true state of affairs was disclosed only when an aspirating needle in the lateral sinus drew forth pus. Thrombosis was present despite the fact that the tunica adventitia presented a normal appearance. An early diagnosis is of paramount importance. The Tobey-Ayer test was of no value in this case and may be misleading. Headache was not complained of. Papilledema, which was present, is seen more frequently with sinus thrombophlebitis than with either cerebellar or temporo-sphenoidal lobe abscesses. Metastatic arthritides were present and were represented by a subcutaneous abscess of the ankle and, later, by an arthritis of the sternoclavicular joint. The sternoclavicular joint is the one that is involved most frequently with lateral sinus thrombophlebitis. It rarely suppurates and has been referred to as a toxic arthritis.

*Stewart Treatment for Osteomyelitis: Preliminary Report. L B Kline—p 251.

Treatment for Osteomyelitis.—Kline employed in fourteen cases the trinitrophenol: calcium carbonate treatment for osteomyelitis described by Stewart. The trinitrophenol solution

was sprayed into the wound from an ordinary nasal spray. In large wounds it was poured in. When lesions were deep in the tissues and drained through fistulous tracts, a soft rubber catheter was used and the solution was injected by means of a 5 cc. Luer syringe. The calcium carbonate suspension was applied to the wound immediately following the application of the trinitrophenol solution. The author has observed that granulation tissue forms promptly, purulent exudate is reduced, healing is rapid, pain and discomfort are minimized and the residual scar is less marked. He encourages free exercise of the affected part. The almost complete absence of pain permits better cooperation. He has used these mixtures in the treatment of ordinary infected wounds with satisfactory results

Coarctation of Aorta.—Hardaway and Sawyer cite a case of coarctation of the aorta with a developmental defect in the urinary tract. The patient died before any detailed observations could be made. Death was distinctly cardiac with progressive edema of the lungs that did not respond to medication. The blood pressure registered 300 mm. of mercury. There was a distinct narrowing of the descending arch much like a ligature that had been tied around the aorta and there was almost a complete septum within the lumen of the vessel; this septum contained an aperture about the size of a small goose quill. The pressure encountered by the blood stream resulted in marked collateral circulation with enlargement of the intercostal vessels and definite erosion of the right fifth rib and the left fifth and seventh ribs, which was manifested by roentgenograms, which showed the erosion definitely. It seems evident to the authors that a case of coarctation has the following diagnostic points that should lead to a definite diagnosis during life: (1) high blood pressure in the upper extremities with a slight discrepancy between the two arms and a marked discrepancy between the upper and lower extremities, (2) hypertrophy of the heart, (3) marked increase in the collateral circulation, and (4) erosion of the ribs. Postmortem examination revealed atrophy of the left kidney (apparently congenital), atresia of the left ureter due to the atrophy of the kidney, and fetal type of hypoplasia of the right kidney (arrested development).

Eruptions from Drugs.—Wise and Sulzberger state that increasing knowledge of immunobiologic and sensitization phenomena has led to more or less obliteration of what at one time was regarded as a sort of dividing line between dermatitis medicamentosa and dermatitis venenata. The authors use the term "drug eruptions" to indicate all cutaneous (and mucosal) manifestations in the subject, without regard to the path taken by the drug, whether by oral administration, by injection, by external contact or by combinations of these. Among the toxicodermas, the allergic, anaphylactic eruptions, all those based on a hypersensitivity, predominate. The character of the manifestation depends on the terminal organ on or in which the hypersensitivity reaction takes place. Consequently, the hypersensitivity manifests itself in different types of reaction, as asthma, in the bronchial form; through phenomena on the part of the digestive canal, in the gastro-intestinal form; as hay fever, in reactions of the conjunctiva and the nasal mucosa; and, finally, in the form of definite skin reactions. The origin of one specific hypersensitivity may facilitate polyvalent specific sensitizations for further substances. There are certain phenomena in cutaneous hypersensitivity that apparently oppose the accepted concept of anaphylaxis and allergy, at least so far as the preservation of specific or monovalent sensitization is concerned. The cardinal eruptions caused by drugs ingested or injected are: 1. Truly eczematous eruptions with erythema, vesiculation, weeping and scaling are due to quinine, procaine hydrochloride, ephedrine, mercurials and sometimes arsphenamines. 2. Urticarial eruptions may be caused by belladonna, atropine, the morphine group and phenolphthalein. 3. Scaly erythematous eruptions, purely erythematous or scarlatiniform, and morbilliform and dermatitis exfoliative-like conditions are induced by arsenic, arsphenamine, belladonna, balsams and the heavy metals. 4. Phenolphthalein, antipyrine and salicylates produce erythema multiforme-like eruptions. 5. Erythema nodosum-like eruptions are due to iodides and bromides. 6. The effect of acneiform, furunculoid and erysipelas-like eruptions is due to bromides, iodides, chlorine, oils, tars and so on. 7. The causal drugs in ulcerating and vegetating eruptions are bromides and iodides. 8. Purpuric eruptions may be due to iodides, arsphenamines, particularly sulpharsphenamine, and balsam. 9. Phenolphthalein, antipyrine and sometimes the arsphenamines induce fixed and circumscribed, erythematous or bullous and polychromatic pigmented eruptions. Eruptions due to external medicaments and other irritants include almost all well defined chemical substances, such as mercury, resorcin, butesin, butesin picrate, trinitrophenol, sulphur, chrysarobin, procaine hydrochloride, nupercaine and so on. There are many cases of eruptions in hypersensitive persons due to applications of medicinal salves, lotions, proprietary remedies and cases caused by skin contact during injection, but the overwhelming majority of the cases of eczematous dermatoses occur as industrial dermatoses.

Many eczematogenous substances can be eliminated and many cases of dermatitis avoided by the patch test. The patch test permits of the choice and employment of the least deleterious substances.

Progressive Pseudohypertrophic Muscular Dystrophy.

—Lutz uses the epinephrine-pilocarpine treatment in practically all stages of progressive pseudohypertrophic muscular dystrophy. Administration has been by daily intramuscular injection of from 0.2 to 0.3 cc. of a solution containing one part of a 1 per cent solution of pilocarpine hydrochloride and two parts of a 0.1 per cent solution of epinephrine hydrochloride. He considers from six to eight weeks a "course of treatment." The patient is asked to return at monthly intervals for observation and is cautioned to continue the daily physical drill that was taught him during his stay in the hospital. Usually, after an interval of two or four months the disease starts to progress and the patient is admitted for another course of injections. The author has noted a definite clinical improvement in all his cases, and in two patients the improvement was so marked that they might have been classed as cured except for the fact that at the end of four months they returned with the disease again showing a slight progress. He believes that the glycine treatment sounds much more logical and has a much more scientific basis or excuse for its use than the epinephrine-pilocarpine method but lacks in clinical results. He considers the daily injection of pilocarpine and epinephrine a valuable treatment for pseudohypertrophic muscular dystrophy and that it will give symptomatic relief. Sufficient time has not elapsed to tell whether it will prolong life or alter the mortality rate, but it is fairly reasonable to assume that a child who is able to walk about stands a better chance than one who is not able to move from its bed.

Nocturnal Enuresis.—Earl, in stressing the value of psychologic treatment in nocturnal enuresis, discusses the incidental, causative, psychologic, regressive, physical and psychiatric factors. Such treatment should be carried out by a children's psychiatrist, or at a child guidance clinic. For the simple case of enuresis uncomplicated by other behavior disorders, simple suggestion, superficial and symptomatic though it may be, is adequate and efficient. The exact manner of its application may be used quite formally, as in hypnosis, or disguised under the name of medical treatment or training, having only the suggestive power as its common basis. The author believes that enuresis belongs definitely to Babinski's pragmatic definition of "pithiatism" as overt symptoms which can be "caused by suggestion and cured by countersuggestion or by persuasion."

 *Chloroform Hypocne Amnesia in Labor. J. Clark.—p. 468.

Comparative Study of Tuberculin Tests.—Kayne and Weill-Hallé believe that the Moro test is the least sensitive of the three tuberculin tests commonly employed. The Pirquet (pure tuberculin) and the Mantoux test (1:1,000) are about equally sensitive, the Mantoux (1:100) being definitely more sensitive. For use in infants and young children the Moro test has definite disadvantages as regards technique and interpretation of results. When employed, a control test with ether only should be carried out. The Pirquet test is, for infants and young children, the simplest and easiest test to perform and therefore should be employed first. If found to be negative, an intradermal test with a dilution of 1:100 should be carried out. In older children it is worth while to repeat the test, if still negative, with a dilution of 1:10. The Mantoux test in a dilution of 1:10 should be carried out with a control injection of the broth used for the preparation of tuberculin. A Pirquet test should be regarded as positive only if there is at least 1 mm. of erythema on each side of the scarified area. The minimum required for a positive Mantoux test with any dilution is an area of erythema 10 mm. in diameter, associated with some swelling to touch or a well defined erythema greater in area than this. Reactions showing an erythema 5 mm. in diameter or more should be regarded as doubtful and retested on the fourth day and, if they are still doubtful or negative, the test should be repeated with a stronger dilution. If a reaction obtained with a dilution of 1:10 is definitely more marked on the fourth day than the control test, but still under the limit of a positive reaction, it is advisable to regard the test as doubtful and repeat it either within ten days or three months. The authors suggest that, instead of maintaining the controversy as to the relative value of the Pirquet and Mantoux tests, physicians should combine the two, the Pirquet test being followed by the Mantoux test 1:100 and adopted as a routine under a different name—for example, "the combined tuberculin test" or "the cutaneous intradermal test."

Chloroform Scopolamine Amnesia in Labor.—Clark presents a modification of the scopolamine method of amnesia in labor that is suited for home treatment. In ten years he has

conducted eighty-four confinements in accordance with the following method: Treatment is commenced when the patient complains of pains that are regular and of moderate strength. The strength and duration of pains are gaged best by abdominal palpation. The patient is put to bed. One nurse is in attendance. An initial light anesthesia is induced by chloroform until the patient is quiet and sleeping between pains. A hypodermic injection of $\frac{1}{100}$ grain (0.00065 Gm.) of scopolamine is given as soon as the patient is lightly under. The scopolamine is repeated in doses of half this amount at intervals varying from half an hour to an hour. The ideal aimed at is that the patient should be drowsy and quiet between pains. Any indication of returning awareness can be controlled by immediate inhalations of chloroform and a subsequent injection of scopolamine. Chloroform controls any restlessness that scopolamine may produce. The initial administration of chloroform seems to have a subduing effect throughout. As labor progresses, the dose of scopolamine is diminished to $\frac{1}{500}$ or $\frac{1}{400}$ grain (0.0002 or 0.00015 Gm.) and the intervals of injection are lengthened or shortened according to the judgment of the practitioner. The author has always avoided giving any scopolamine during the hour immediately preceding delivery and administers light chloroform from the time that the anus assumes the D shape until the head is born. If labor is delayed, solution of pituitary may be used. The author states that in no case does the amnesia seem to affect the condition of the infant at birth. The delivery of the placenta is often delayed, but not unduly so. The mother sleeps or remains drowsy for some time. The amnesia lasts beyond delivery for a period that is directly proportionate to the extent of the amnesia induced during labor. The mother usually emerges from her amnesia with a strongly expressed disbelief that her baby has arrived.

Calcium in Epilepsy.—Griffiths made repeated observations of serum calcium on a group of forty-eight young epileptic patients who were living a normal school and outdoor life in an epileptic colony. Samples of blood were taken at various times of the day and at varying intervals over a prolonged period, in the hope of obtaining a sufficient number of observations so that the time of the fits could be correlated. Estimation of 433 serum calcium readings was obtained. It was observed that the average serum calcium falls within normal limits, though the range of values is wide and variable, for the group and for individuals alike. The average of values before a fit is found to be greater than that after a fit. The highest range of values is that obtained during a succession of fits, while low values are found after successive fits. In two cases that terminated fatally, estimations made during successive fits proved to have definitely low values. When cases of fits by day are contrasted with those by night, the averaged figures show that the behavior of the serum calcium in relation to the attacks varies inversely in the two groups. This inversion is confirmed in a striking manner in one particular case, which gives low values after day fits, high values after night fits and a persistent median value in intervals free from fits. Treatment with large doses of calcium may have beneficial results, while the diminution of serum calcium by sesquiphosphates is definitely detrimental. Serum phosphorus is found to be within normal limits, though with a wide range of variation. Its relation to the serum calcium is not always disturbed by fits, though abnormal ratios may be associated with attacks.

Hydrogen Ion Concentration of Cerebrospinal Fluid.—Harris and his co-workers maintain that the current teaching according to which the spinal fluid is more alkaline than blood

is erroneous. They believe that their figures are reliable, because they employed a method for the determination of p_{H} which is superior to those available to previous workers in the same field. So far as they are aware, none of these investigators used the glass electrode. The glass electrode was employed and was adapted for the use of blood and spinal fluid. To avoid loss of carbon dioxide, the method used was as follows: The ordinary cannula in use for cerebrospinal work was employed. Connected to it was a piece of fine rubber tubing of a narrow bore, about 3 inches in length. The distal end of the tubing was inserted in the inner chamber of the electrode. This chamber fills up with fluid and overflows, so that the fluid whose p_{H} was taken never came in contact with air. Twelve inpatients were investigated. Only once did the p_{H} exceed 7.4, all the others being below this figure. There was a definite relation between the p_{H} of spinal fluid and that of blood and the latter was more on the alkaline side than the former. It is impossible to establish absolute values for the p_{H} of the spinal fluid unless the acid balance of the blood also is determined. As is to be expected, there is no relationship between lactic acid and the p_{H} reading. The authors state that an explanation why the cerebrospinal fluid is more acid than blood may be found in the difference of behavior of carbon dioxide in these two fluids. The lactic acid contents of cerebrospinal fluid and blood are approximately the same, provided sufficient time is allowed for an equilibrium between the two fluids to be established.

*Branchiogenic Cancers and Other Carcinomas of Neck of Cryptic Origin. J. B. Cleland and B. S. Hanson.—p. 241.

Venoms of the Broadheaded Snake (*Hoplocephalus Bungaroides*) and of the Yellow-Banded Snake (*Hoplocephalus Stephensi*). C. H. Kellaway.—p. 249.

Branchiogenic Cancers and Carcinomas of Neck.—Cleland and Hanson believe that a common explanation of the occurrence of at least some of the carcinomatous and squamous epithelioma growths of the neck is that they are derived from the epithelium of a branchial cleft. In the majority of cases the malignant growths in the neck are clearly secondary to recognizable primary growths in neighboring structures, or sometimes to those at a distance. Tumors of the carotid body have characteristics of their own. In or near the midline or close under the jaw growths may arise from remnants of the thyroglossal duct or from outlying portions of a duct of a salivary gland, but by the time treatment is sought the size of the growth precludes a recognition of such an origin. Occasionally cases of carcinoma in the neck may originate from remnants of the branchial epithelium; in fact, the total absence of such carcinomas would be remarkable. The occurrence of branchial cysts is an indication that the branchial clefts may be closed imperfectly. Apart from the formation of actual cysts, islands of epithelial cells may be left behind as the branchial cleft closes, and late in life these dormant cells may be stimulated into activity and be responsible for branchiogenic cancers. Dental cysts, lined by squamous epithelium and surrounded by plasma cells, are believed to originate from irritation, usually caused by infection, of groups of epithelial cells left behind by the enamel organ during development. A recent alternative theory is that the cysts are really the ends of sinuses lined by epithelium which has descended from the surface of the gum. A frank squamous epithelioma may develop rarely in the squamous epithelium lining a relatively innocent cyst. It is possible that a small and unrecognized branchial cyst of long duration may be responsible at times for a squamous epithelioma, the mass of growth soon obliterating the cavity and a solid growth of cryptic origin resulting. Some presumed branchiogenic cancers are cystic, probably from sec-

ondary degeneration. The possibility of the healing of small primary growths, some of whose cells may have escaped previously into the draining glands, is considered. Though it is perhaps possible for a small epitheliomatous ulcer to undergo healing from destruction of the malignant cells by fibrosis, the likelihood of this occurring must be small. In accessible sites, healing of malignant growths probably does occur from time to time. The possibility of the introduction of cells from the malpighian layer of the skin into the lymphatics as a result of trauma must be considered; for instance, puncture wounds by spicules of bone during eating. From time to time examples of inclusion or implantation cysts in the subcutaneous tissue are seen resulting either from nipping off of a little epithelial fragment during surgical operations or from pushing into the tissues, that is by the blunt end of a needle, of a little group of cells from the deeper layer of the surface epithelium. It is possible that such puncture wounds may sometimes carry epithelial cells into the lymph spaces, whence they may be carried to the draining glands and there grow.

Mantoux Test in Assessing Allergy in Tuberculosis.

Westwater has used the Mantoux tuberculin test as a means of assessing allergy in tuberculosis. He emphasizes Zinsser's definition that the allergic state is "an increased capacity to react against an antigen released by the disintegration of the bacillus." This disintegration will require an active resistance to break through the lipid sheath of the bacillus and release the protein; it is the release of this protein which gives rise to the allergic reactions. The author regards allergy as the common property of infected persons; whether they are diseased or not depends on their resistance. From 80 to 90 per cent of the adult population are known to be allergic but have not tuberculous disease, so that in man successful resistance is not contingent on a lack of allergy. This allergic property, however, in its variations reflects the activity not of the infection but of the immunity response. From clinical results in children there is the suggestion that the higher degrees of allergy are found only with active resistance—with disintegration of the invading bacilli. When the immunity mechanism is not active, i. e., in the stage of quiescence and latency, allergy tends to wane, but the property is still there. The same interpretation can be placed on the results in adult phthisis—increased in allergy occurs only in cases responding to treatment—i. e., in cases showing active and to a varying degree successful resistance. On the other hand, when resistance is overcome and swamped, allergy wanes, as presumably the invading bacilli are not being broken up to the same extent. In tuberculosis then there are the three factors: infection, immunity and allergy or sensitivity. Infection is directly opposed to immunity; allergy is a property that may perhaps be inconvenient to the immunity mechanism. These results suggest that allergy or sensitivity to the tubercle protein is probably a minor factor in the pathology of tuberculosis.

Inversion of T Wave in Lead 3.—Clerc and his collaborators selected only those electrocardiograms which showed inversion of the T wave in lead 3 with so-called right axis deviation or the latter alone without other abnormalities. This group comprised twenty-six patients, fifteen with the combination and eleven with right axis deviation alone. These changes were found to correspond to cardiopathies based on mitral lesions, congenital cardiopathies, congenital or acquired lesions of the pulmonary artery, or secondary cardiopathies resulting from chronic pulmonary or thoracic alterations. In the first group of fifteen patients with negative T wave and right axis deviation there were six fatalities, while in the second group of eleven with right axis deviation alone there were no deaths. The authors therefore believe that there is a definitely poor prognostic significance attached to this type of electrocardiographic abnormality.

Intra-Arterial Pressure: Control of Indirect Methods. R. Giroux.—p. 1388.

Paragangliomas and Epinephrine hypertension.—Bauer and Leriche describe a case of paroxysmal hypertension in a man, aged 40. The crises began with epigastric malaise, mild nausea, pallor of the face and extremities, coldness to touch, pounding heart, ocular pulsations, sweating and often mild trembling of the fingers. They lasted from half an hour to an hour and a half, after which a heavy feeling in the head and marked lassitude persisted for several hours. They began in the mornings. Between the attacks the pulse was 72 to 88 and the pressure 160-180/115-125 mm. of mercury. During the crisis the systolic pressure rose more or less while the diastolic pressure remained the same or fell a few millimeters. The pulse did not change in mild attacks but was notably slowed in the severe ones. The authors believe that quite likely they were dealing with essential paroxysmal hypertension of suprarenal origin. Localization of the suspected tumor was not possible. Finally it was decided that operative investigation of this possibility was justifiable. After an unsuccessful attempt on the right side (the suprarenal appeared normal) a tumor was found in the left suprarenal. This was removed and found to have all the characteristics of a paraganglioma. The results of the procedure were good and the patient returned to a normal state. The authors state that the diagnosis is difficult but rests on the constant or lowered diastolic pressure during the attacks, a bradycardia, a paroxysmal and transitory hyperglycemia and perhaps also an increase in the leukocytes and erythrocytes. The advisable therapy is operative because of the poor prognosis when any other form of treatment is used. Removal of a normal suprarenal must be guarded against in these cases.

Electroneurolysis in Therapy of Trigeminal Neuralgia.—Fracassi and Marelli treat essential trigeminal neuralgia by electroneurolysis with the following technic: The

patient lies on his back on a flat table with the head in such a position that the involved nerve forms the continuation of a vertical line with the needle introduced vertically. This position of the nerve in relation to that of the needle is obtained by the inclination or by the elevation of the patient's head without changing the position of his body and is controlled by the position of the foramen ovale and the foramen rotundum. To approach the inferior and superior alveolar nerves the patient's head is inclined in the first case and raised in the second case 15 degrees from a line horizontal to the axis of his body. The needle used is one of those commonly used for intramuscular injections, not exceeding 4 or 5 cm. in length. A fine insulated copper wire, which can easily pass through the eye of the needle, previously disinfected with alcohol, is used as a mandrin. The layer of insulating thread of the mandrin is removed at one end 3 or 5 cm., and a knot made in the mandrin as a mark to indicate the length which should be introduced in order to have its point pass the point of the needle. The other end of the wire is then connected with a galvanic current. A painful sensation of the patient, exteriorized by an involuntary gesticulation, indicates that the point of the mandrin is in contact with the involved nerve. The current is then stopped in order to perform the anesthetization of the nerve by infiltration of 1 cc. of a 2 per cent solution of procaine hydrochloride-cpinephrine. Four or five minutes later the isolated mandrin is introduced down to the mark previously made on it. The other end of the wire is then connected to a galvanic current and this current is permitted to pass in a slow and progressive form until 5 milliamperes has been given during three or five minutes at each pole. The positive pole should be applied before the negative one, because the former adheres to the nerve and it is detached from it only by the passage of a negative current. Because of the fineness of the mandrin, the galvanic current does not destroy the tissues of the nerve during the first application. A second application, given three or four days later with the same technic, results in the destruction of a new zone of the nerve and the complete disappearance of the pain. In the authors' cases the pain has not reappeared up to the present (six months after the treatment). They advise resorting to alcoholization of the nerve with 2 or 3 per cent phenolated alcohol in cases in which the galvanization is impracticable. Phenolated alcohol is more efficient than absolute alcohol in these cases.

Genesis of Hyperemesis of Pregnancy.—Schultze-Rhönhof points out that some investigators assume a purely psychic while others assume a purely organic cause of hyperemesis of pregnancy. He believes that as a rule both factors are involved but considers the psychic factor the more important. That organic factors are involved is proved by the fact that vomiting is a rather frequent occurrence in pregnancy, and hyperemesis is really only an exacerbation of this vomiting. Many women are subject to nausea before they are aware that they are pregnant. This early nausea is no doubt the result of the presence of toxic substances that sensitize the center of vomiting and the vagus and thus reduce the threshold of irritation so that psychic influences lead to vomiting more readily. The predominating importance of the psychic component in hyperemesis is indicated by the fact that as a rule hyperemesis does not become manifest until the woman is aware that she is pregnant. The author noted also that hyperemesis is comparatively rare in unmarried pregnant women. He thinks that the greater incidence in married women is due

to the fact that married women get more attention and sympathy from their environment, particularly the husband. The motivating factors may differ, the woman may want to call her husband's attention to the great sacrifice on her part, or she may have a desire to get even and make her husband share in her discomfort. The woman is of course rarely conscious of such desires. One of the most important factors in the development of hyperemesis is that she is given attention by her environment if she gets severe attacks of vomiting. Taking her out of her environment often results in cure within a comparatively short time, while a visit from the family often results in a relapse. In some cases the hyperemesis may be a defense mechanism, the manifestation of an aversion against intercourse, which develops in some pregnant women. An escape into illness makes it possible for the married woman to reject the intercourse. The greater incidence of hyperemesis during the first pregnancy is a further proof of the significance of the psychic factor, for the woman usually has to overcome greater psychic conflicts. Moreover, hyperemesis is rare in psychically well balanced women. The author admits that his theory does not necessarily apply to all cases, and he does not exclude the possibility of a different pathogenesis for some cases.

Heating of Deeper Parts in Short Wave Field.—Schultze-Rhonhof and Rech report observations which indicate that the application of a 30 meter wave in the short wave field does not produce a measurable heating of the deeper layers of the tissues. Such an effect had been demonstrated in preliminary experiments on bread. The fact that this is not the case in human tissues proves the great significance of the heat regulators of the human organism. This lack of heat action on the deeper layers in short wave therapy of abdominal organs concerns of course only the mechanism of the therapy and does not involve a criticism of the efficacy of the treatment, which is often quite clear. The authors' experiments provided only a certain insight into the thermo-electric but not into the electrochemical actions of the short wave therapy.

Renal Function in Toxicoses of Pregnancy and Eclampsia.—On the basis of his studies de Snoo reaches the conclusion that for clinical purposes the bromide lye method is entirely satisfactory for the determination of urea in the blood. This was determined in comparison with the urease method. The author observed that in simple toxicoses the disturbances of the renal function are rarely severe and that in chronic hypertension, even in cases presenting severe uremic disturbances, the renal function is as a rule only slightly or not at all impaired, but that in women who have passed through an eclampsia the renal function is in general severely impaired as to the elimination of water and the secretion of urea. In the latter group of women, the urea content generally increases up to the second, third or fourth day, and after that it decreases again, irrespective of whether the women have been delivered or not. The secretion of urine becomes normal sooner than the elimination of the urea. The author thinks that the increase in the urea content of the blood is not dangerous and that the prognosis is dependent to a greater extent on the diuresis than on the urea content. He found also that in many cases of eclampsia the renal function may be entirely normal before the onset of the convulsions and that the convulsions exert no specific influence on the kidneys, but that the same functional disturbances may occur without convulsions. He thinks that renal disturbances may be caused by vasomotor disorders, particularly vascular spasms, and that the parenchymatous organs of pregnant women with toxicosis are especially susceptible to such vasomotor disorders. He shows further that disorders of the kidney may develop as the result of thirst and vomiting and in the absence of a urea retention, and that the urea content of the blood is a valuable aid in estimating the seriousness of hyperemesis of pregnancy.

p. 361.

Eosinophils Following Epinephrine Tolerance Test.—Von Krompaszky decided to study the relation between the suprarenal system and the eosinophile cells, and particularly whether the epinephrine eosinophilia changes in the course of certain diseases. In healthy children it was found that the injection of epinephrine increases the number of eosinophils and that the number of leukocytes increases, as a rule, but not as regularly as does the number of eosinophils. Tests on children with tuberculosis revealed that in one group the effects of epinephrine were the same as in the healthy children, while in a second group an entirely different behavior obtained in that the epinephrine injection was followed by a decrease in eosinophils. It was found that the majority of the children belonging to the first group had a mild tuberculosis, while the majority of those belonging to the second group had a severe form of tuberculosis. In determining the causes of the effect of epinephrine on the eosinophils, the author points out that under the influence of epinephrine the bone marrow eliminates greater amounts of leukocytes, which becomes manifest in the appearance of an increasing number of young leukocytes. The fact that in severe forms of tuberculosis there is no increase in the number of eosinophils after injection of epinephrine is probably due to impairment of the leukopoietic apparatus.

Tetany After Feeding with Fruit Juices.—Bäuml compared the constituents of a fruit juice extract that had been recommended as a substitute for mother's milk with those of mother's milk. He found that the so-called fruit-milk is nearly equivalent to human milk as regards the nutritive substances, the calories and the minerals. It differs from human milk mainly in one factor, its calcium deficiency. Whether this mixture of fruit juices reaches the biologic value of human milk depends on three factors: (1) whether feeding with the fruit-milk results in the normal development of the nursing, (2) whether it can replace mother's milk in nurslings with nutritional disturbances and (3) whether it will prevent rickets and tetany. The author cites a case history which reveals that a nursing, who since the end of the second month of life had been fed with the fruit-milk, had a mild form of rickets and also manifested symptoms of tetany at the end of the fifth month. This indicates that the fruit-milk does not prevent rickets and tetany and thus does not have the biologic value of human milk.

*New Method of Percussion. Hasse.—p. 1273.

Funicular Spinal Disease and Its Therapy.—Illing describes the histologic aspect of funicular spinal disease and shows how it differs from the changes characteristic for tabes and for multiple sclerosis. Parallelism between the clinico-neurologic and the anatomic aspects is often missing in funicular spinal disease. Moreover, this disorder is frequently only a symptom of an internal disorder. In more than half of the cases it concurs with pernicious anemia, but the author is

primarily interested in the cases in which funicular spinal disease is the only disorder and in which achylia, psychosis and disturbances in the hematopoiesis are absent. He observed four cases of this nature. The first symptoms of the disease appeared from six to twelve months before admission to the clinic. Three patients, women of the menopausal age, complained of a feeling of numbness or of formication in the feet and hands and of weakness in the legs and arms, and one complained of occasional urinary incontinence. The serologic tests for syphilis were negative. The neurologic manifestations were most severe in the legs. In two patients the symptoms of an involvement of the dorsal funiculus predominated, but they were mixed with spastic symptoms. In the other patient spastic symptoms predominated. Since vitamin B has an antineuritic effect, the author decided to try treatment with yeast in the three women. They were given yeast three times each day, and considerable improvement resulted. It is assumed that the yeast treatment arrested the further progress of the spinal disorder. The author admits that a complete cure cannot be expected, since nervous tissue, once destroyed, cannot be repaired, but in new cases the paresthesias may disappear. He suggests that the funicular spinal disorders in which pernicious anemia is absent may be the result of avitaminosis.

Treatment of Gastric Ulcer.—Bogendörfer resorted to the intramuscular injection of a histidine preparation in patients with gastric and duodenal ulcers. He used a preparation 1 cc. of which contained 0.04 Gm. of histidine monohydrochloride. The daily administration of 5 cc. caused no undesirable complications. The author employed the treatment in about thirty cases. All other medicinal treatments were discontinued while the histidine preparation was administered. The result was that the pains disappeared rapidly, and within a comparatively short time the patient could be put on an ordinary diet. The author gives brief clinical histories of three cases which indicate that the patients could be discharged from the clinic in from two to three weeks. A satisfactory explanation of the action mechanism of this treatment is still lacking, but experiments are now being conducted to determine the influence exerted by the preparation on the gastro-intestinal functions.

New Method of Percussion.—Hasse corroborates the efficacy of the friction method described by Bukovala in the *Minchener medizinische Wochenschrift* (81:1026 [July 6] 1934; abstr. THE JOURNAL, Aug. 25, 1934, p. 636). He asserts that he employed this method with excellent results for thirty years. However, he wishes to call attention to still another aid that is helpful in determining the outlines of organs, particularly in the auscultatory comparison of the two lungs. If the sound tube of the binaural stethoscope is held in the fold between the right thumb and the hand, it is possible to percuss the forefinger of the left hand with the middle finger of the right hand. The conduction of the percussion sound by the middle finger, the sound tube and the tubing into the two auditory meatuses increases the intensity of the percussion sound by two or three times its volume, so that this method permits the perception of sound values that otherwise cannot be heard. The author thinks that this rather simple procedure is helpful in the usual methods of percussion as well as in the friction method. Control tests before the roentgen screen corroborated the fine differences detected with the described method.

Arrest of Hemorrhages in Hemorrhagic Diathesis and Hemophilia by Vitamin C.—The favorable effects produced with the parenteral administration of vitamin C (ascorbic acid) on capillary hemorrhages induced Böger and Schröder to try this therapeutic method in other hemorrhagic diatheses. In a case of Schoenlein-Henoch's purpura, they found that the daily

intravenous administration of 100 mg. of an ascorbic acid preparation effected a rapid disappearance of the manifestations of the capillary toxicosis. This was the more surprising since the oral medication with vitamin C had been ineffective. The failure of the oral medication may be the result of the gastro-intestinal disturbances that frequently accompany the avitaminoses. The authors succeeded also in arresting severe intestinal hemorrhages in a hemophylic patient with the daily intravenous injection of 150 mg. of the ascorbic acid preparation. In a patient with "acute" essential thrombopenia, in whom there existed an almost complete lack of thrombocytes and severe hemorrhages of the skin, the mucous membranes and the kidneys, the daily intravenous injection of 150 mg. of the ascorbic acid preparation accomplished the cessation of the hemorrhages within four days. This case is especially noteworthy because the hemorrhages ceased before there had been an increase in the blood platelets. The increase in the thrombocytes did not take place until two days after the complete cessation of the hemorrhages. The authors conclude from this that thrombocytopenia is not the only factor in Werlhof's disease but that a permeability of the vascular walls is likewise of some importance. They think that vitamin C exerts an influence on the vascular permeability but also modifies the albumin factor in the plasma. They hope that the parenteral vitamin C therapy of hemorrhagic disorders will be tried in other clinics.

Psittacosis.—Gutzeit and Johannsen report an increased incidence of psittacosis in Berlin during the first few months of 1934. In discussing the roentgenograms of psittacosis pneumonia, the authors point out that in contradistinction to the rather atypical clinical symptoms, which resemble those of bronchitis, the roentgenograms are typical. They show extensive infiltrative pulmonary processes either on one side of the lung or many, sometimes successively developing, small areas of denseness on both sides. The structure and the outlines of the infiltrates of psittacosis are characteristic and can be differentiated from those of bronchopneumonia and of lobar pneumonia by their uniform and finely granulated structure. At the onset of the infiltration a fine veil of denseness, without foci of greater denseness, seems to be spread over the still visible, normal structure of the lung. As densification advances the veil extends further and gradually covers the structure of the lung, but there is always a characteristic uniformity of denseness. The treatment employed by the authors was purely symptomatic. During the severest stage, when a general toxicity predominated, circulatory and cardiac remedies were given also as in the typical pneumonias, quinine and urethane, packs of the chest and cold spongings. Small doses of amidopyrine proved helpful in reducing the fever. The clinical diagnoses of the cases observed by the authors were corroborated in animal experiments. The birds that were the source of infection had been in contact with some of the patients for nine months. The authors conclude from this that the virus is eliminated only at times, and they point out that parrots may be carriers of the virus without showing signs of the disease. They suggest measures for the prevention of psittacosis.

Roentgenotherapy of Ankylopoietic Spondylarthritis.—Haenisch employed roentgenotherapy in thirteen rather severe cases of ankylopoietic spondylarthritis. In three patients the treatment proved ineffective, but in two of these the period of

observation and treatment has been too short to permit a definite evaluation. In the remaining ten cases the subjective complaints were considerably improved, so that the patients were highly pleased with the results. Many requested a repetition of the irradiation as soon as the improvement seemed to subside. Two patients have been under the author's observation for more than four years. Some patients had been subjected to other treatments without satisfactory results, and they stated of their own accord that the temporary or prolonged improvement was the result of the irradiation. But the author admits that, as far as he is able to judge, the ankylopoietic process advances in spite of the treatment, the reduction in pain and the improvement in the general condition. Of course, it is impossible to estimate whether the anatomic changes in the skeleton are retarded by the roentgen treatment or not, but he thinks that his observations justify a trial with roentgenotherapy in suitable cases of ankylopoietic spondylarthritis. He recommends the following method of irradiation: The rays are applied to three or four fields along the spinal column and eventually to one or two fields on the right and left sacro-iliac synchondrosis. The fields are 10 by 12 or 10 by 15 cm. To each field 130 roentgens is applied five times. The irradiations are given from a distance of 30 cm., through a filter of 0.5 mm. of copper and 1 mm. of aluminum, and with 0.9 mm. of copper as the half layer value. The intensity is such that from 28 to 35 roentgens is applied each minute. The intervals between the irradiations of each field are from five to ten days. The joints react occasionally to from six to ten applications of 65 roentgens, applied under the same conditions. The series of treatments may be repeated after six months, but a definite rule is difficult and the result of the treatment and the severity of the condition should be taken into consideration.

Treatment of Actinomycosis.—After evaluating various methods of treatment, such as surgery, medication with iodine, injection of methylene blue and vaccination, Dyes expresses the opinion that the results obtained with roentgenotherapy are such that the treatment hardly requires further recommendation. From the standpoint of the roentgenologist, actinomycosis takes a special position among the inflammatory disturbances in that it requires much larger quantities of roentgen energy than do other inflammatory conditions. According to the dose of roentgen rays that was employed, the author reports three groups of cases. In the first group the entire unit skin dose was applied, either in one session or within six days. These patients recovered within from three to ten weeks. The second group includes the patients in whom from 40 to 60 per cent of the unit skin dose was given, either once or several times in several sessions with intervals of several weeks' duration. The fact that the irradiation had to be repeated indicates that the single dose was not sufficiently large. The patients belonging to the second group recovered in from nine to sixteen weeks, and relapses did not occur. In the third group of patients, the single dose did not reach 40 per cent of the unit skin dose, and in most cases 25 per cent was applied, either once or repeatedly after intervals of several weeks. The actinomycosis was cured in all ten cases that were treated in this manner, but in one case a relapse occurred six months later. The observations on these three groups of patients prove that the large dose accelerates the cure considerably.

Hydrometra After Intra-Uterine Radium Irradiation.—Vogt gave intra-uterine radium irradiations to a woman who had undergone an operation for bilateral ovarian carcinoma, and a hydrometra developed. The author considers this a rare occurrence, since it was the only case in which he observed it. The differential diagnosis of hydrometra may present great difficulties. If the uterus remains after the removal of both adnexa on account of carcinoma, the later enlargement of the uterus generally leads to the assumption of a myoma or of a relapse of the ovarian carcinoma. In the course of the operation for the removal of the uterus, after the development of the hydrometra, it was found that the postoperative irradiation with roentgen and radium rays, to which the woman had been subjected after the operation for ovarian carcinoma, had produced good results.

Action of Intravenous Injection of Radon on Blood.—Nemenow and Gurewitsch describe experiments on rabbits

which reveal that the intravenous injection of radon effects a reduction of the number of leukocytes, especially the small lymphocytes. Histologic studies of the blood forming organs disclose that the changes observed correspond with those of the circulating blood. The lymph nodes and splenic follicles are most severely changed, but the bone marrow is likewise involved. The authors point out that their method of influencing the blood by the intravenous administration of radon is valuable in studies on the hematopoiesis but that the problem of the therapeutic application of radon by means of intravenous injection is still unsolved. They are convinced that the intravenous application of radon is of no value in the treatment of malignant tumors. However, they think that in leukemia, particularly the lymphatic form, the therapeutic prospects of the intravenous injection of radon are more promising, and they are now investigating this possibility.

Bacteremia and Blood Picture in Endocarditis Lenta.

—Wydrin reaches the conclusion that *Streptococcus viridans* cannot be considered the specific organism of endocarditis, but he admits that it is the organism that is most frequently found in bacteriologic studies of endocarditis lenta. In all cases in which there are no indications of syphilis, great caution is necessary in the evaluation of a positive Wassermann reaction. A secondary anemia is one of the principal symptoms of endocarditis lenta, and in cases of severe septic manifestations and of reduced resistance it may appear in a severe form. Leukopenia with manifestations of neutrophilia and nuclear deviation to the left with the appearance of staff-nuclear and young forms and lymphopenia are indications of grave danger. Monocytosis with some or numerous endothelial cells and frequently with macrophages indicates an unfavorable prognosis, particularly in cases of progressive anemia and growing septic symptoms.

Tendinous Fibers and Cardiac Sounds.—Bondi considers the old theory that transverse tendinous fibers are responsible for the development of the musical heart sounds, valuable so far as it calls attention to the fact that tendinous fibers and not alone the valvular apparatus are involved in the formation of cardiac sounds. On the other hand, this theory has underestimated the significance of the tendinous fibers, for sounds may be formed by the transverse and under certain conditions by the longitudinal fibers. Moreover, the tendinous fibers play a part not only in the formation of the musical sounds but also in a portion of the rough, that is the ordinary, heart sounds. The direction, the volume and the velocity of the blood are important for the production of a sound phenomenon. In order to produce a sound, the onflow must be as much as possible in the vertical direction and the velocity must be more than 1 meter a second. These requirements must be fulfilled also in the case of musical sounds; but here tendinous fibers of an especial delicacy, with a diameter of approximately 0.01 cm., are required, and those delicate fibers seem to be present only underneath the fibers that are stretched longitudinally. In these cases a lesser velocity, up to about 60 cm. a second, may be sufficient to produce a musical sound. The occurrence of isolated musical sounds becomes understandable when it is considered that the velocity is not sufficient to produce rough sounds from the thicker tendinous threads or in the valvular canal. Other musical sounds may develop as the result of narrow and regular clefts in a valvular membrane or as the result of cut sounds.

Terminal Deflection in Electrocardiogram.—Scherf stresses the great independence of the shape of the terminal, the ST, deflection. This is partly due to the fact that the various external influences modify the T wave more readily and noticeably than they influence the QRS complex. In enumerating the factors that influence the ST deflection, the author mentions the condition of the cardiac muscle, the tonus of the cardiac nerves, the position of the heart (position of the diaphragm), the thickness and the moisture content of the skin, thoracic exudates, action of digitalis and cardiac hypertrophy. The author further discusses the various abnormalities of the ST deflection and their significance. He concludes that abnormalities of the T wave in leads I and II indicate a pathologic condition in the myocardium, but that it is wrong to base a prognosis as to life expectancy on such changes. In patients with coronary thrombosis, for instance, the abnormal T wave and all other clinical signs may vanish within a comparatively short time and the patient may feel well for many years after. The prognosis should take into consideration all other clinical symptoms as well as the electrocardiogram.

Spinal Hemilateral Paralysis of Diaphragm.—Bardenhofer points out that paralyzes of the diaphragm that can be traced to an impairment of the spinal cord are found as a rule only in cases of extensive impairment of the cervical cord, such as the terminal stages of Landry's paralysis, systemic disorders of the anterior horn and syringomyelia. These spinal forms of diaphragmatic paralysis are as a rule bilateral, but the literature reports also unilateral cases. In all these cases, however, other spheres, whose nuclei are near the spinal origin of the phrenic nerve, were involved in the spinal paralysis. Cases in which a unilateral diaphragmatic paralysis of spinal origin is the only neurologic symptom have never been described before, and for this reason the author feels justified in reporting the history of a man, aged 51, in whom an isolated hemilateral diaphragmatic paralysis developed. It is assumed that this paralysis originated in a small myelitic focus.

Simple Ulcer of Bladder.—Pollak points out that, among the many ulcerous processes of the bladder, one was definitely identified by Paschkis as a disease entity. This type is now generally known as simple ulcer. This form of simple ulcer of the bladder is of nonspecific origin, and tuberculosis, syphilis and carcinoma can thus be excluded. However, the genesis, the diagnosis, the pathologic anatomy and the therapy are still in dispute. The author describes two cases of simple ulcer of the bladder, one of which was under his observation for six years. A cystogenic pathogenesis seems to be certain in both patients. A neglected cystitis during the puberal age appears to have been the cause of the simple ulcer in the first woman, and in the second patient the ulcer began with a puerperal cystitis. It has been pointed out by some investigators that

simple ulcer is a gynecologic disease occurring exclusively in sexually mature women. The two patients observed by the author stated that before the onset of menstruation the condition was exacerbated, while the condition was improved during and after menstruation. Moreover, pregnancy effected an improvement in both instances. To the knowledge of the bacteriology of simple ulcer the two cases contributed in that they revealed that the condition is not caused by a definite organism. Colon bacilli and staphylococci were found in one case, while unidentified gram-negative rods were detected in the other. Local disturbances in the blood supply may promote the development and the relapse of the ulcers. The diagnosis must be made by exclusion. After a specific genesis and carcinoma have been excluded, the condition must be differentiated from ulcerous cystitis and from incrustated ulcer. But loosely adhering incrustations occur also in simple ulcer. The usual treatment for cystitis is ineffective in simple ulcer of the bladder. The local application of methylene blue (from 0.25 to 0.5 per cent solutions) is the most satisfactory of the conservative remedies. Electrocoagulation, however, is the most effective method and proved superior even to the excision of the ulcer.

Alkali Reserve of Blood Plasma in Surgical Diseases.—Szold calls attention to a reduction of the alkali reserve of the blood of patients with renal disease. He studied the alkali reserve of the blood plasma of 100 patients in a urologic clinic and at the same time made the various functional tests of the kidney. He found that in urologic surgical disturbances the reduction in the alkali reserve runs parallel with the damage to the excretory organ and with the inhibition of the discharge. Moreover, there is a parallelism between the reduction in the alkali reserve of the blood serum, the lowering of its freezing point and its content in rest nitrogen and in xanthoprotein.

Cirrhosis of Liver with Hemolytic Anemia and Severe Hematinemia.—Hijmans Van Den Bergh and Kamerling describe a patient presenting hepatic cirrhosis of the Laënnec type in whom a severe icterus and macrocytic anemia developed without any sign of hemorrhage. Such symptoms as the intensity of the icterus, the itching of the skin, the relatively slow pulse and the amount of coproporphyrin (hematin derivative) in the blood serum suggested an obstructive icterus. Other symptoms, however, suggested a hemolytic icterus: reticulocytosis, marked urobilinuria without bilirubin or bile salts in the urine, a marked amount of iron salts in the urine and of bilirubin in the blood serum (the latter mainly with a delayed reaction), strong excretion of urobilin in the stools, severe hematinemia and at necropsy a redness of the bone marrow. The authors advance several hypotheses as to the genesis of pernicious anemia: 1. In consequence of the disease of the liver, the hepatopoietic substances may be destroyed. 2. Resorption of these substances may be disturbed by the intestinal mucosa. 3. There may be a lack of the intrinsic factor of Castle, just as in cases of pernicious anemia.

Sodium Chloride Treatment of Addison's Disease.—Touw and Noordhoek Hegt review the literature on the influence of administration of sodium chloride on epinephrectomized animals and the favorable results of increased salt intake on Addison's disease. The authors observed the clinical manifestations and blood chemistry of two patients suffering from Addison's disease during periods of normal, salt-free and excessive salt diets. There was a noteworthy parallelism between clinical improvement of the patients and the rise of the sodium content of the blood after oral administration of large quantities of sodium chloride (from 20 to 35 Gm. daily).

A CONSIDERATION OF THE STONELESS GALLBLADDER

EVARTS A. GRAHAM, M.D.

ST. LOUIS

AND

W. ARTHUR MACKEY, M.B., CH.B.

Fellow of the British Research Council

GLASGOW, SCOTLAND

Several writers have called attention to the frequency of unsatisfactory results after cholecystectomy on patients whose gallbladders showed a minimal amount of change from the normal condition (Whipple,¹ Muller,² Judd,³ Stanton⁴ and others). The observation, therefore, that surgical results in the stoneless gallbladder, on the whole, are not so satisfactory as in those cases in which gallstones are present is not by any means new.

In most other conditions the idea has gained ground that one should attack a disease early in order to obtain the most satisfactory therapeutic results. Alvarez⁵ has even suggested that the same principle holds true in cases of cholecystitis. There is some reason to think, however, that this principle does not hold for diseases of the biliary tract. Indeed, if one were to be guided only by a table of comparative results obtained by cholecystectomy in cases of minimal pathologic change as compared with those which showed marked and definite changes, one might jump to the conclusion that the statistical results proved the point that cholecystectomy should not be undertaken in the early cases of cholecystitis before well marked changes have occurred.

The case, however, is not so simple and it cannot well be decided merely on the evidence of a compilation of statistics. There are several other considerations that must be taken into account. For example, in assessing the proper value to be placed on the operation of cholecystectomy for the relief of symptoms, it is necessary to take several other considerations into account. Obviously the first question to be asked before an operation is performed in a given case is How much does the gallbladder contribute to the symptoms of that particular patient? It is clear that when the patient is suffering

from repeated attacks of severe biliary colic with its associated symptoms the relief of the symptoms occasioned by the removal of the offending agent may be very striking. An example of such a case is one in which a stone is lodged in the cystic duct or in the neck of the gallbladder. On the other hand, if the patient is having only comparatively mild symptoms, regardless of the extent of the pathologic changes that may be present in the gallbladder, the relief of symptoms obtained by cholecystectomy will be proportionately less. Moreover, if the patient happens to have another unrelated lesion that is responsible for many of the symptoms, it is obvious that the removal of the gallbladder will not give satisfactory relief despite the existence of well marked disease in the latter organ. An example of the latter sort in our experience was a patient who had calculi in the gallbladder but also an early tuberculosis of the spine which became progressive. Finally also there are the patients whose symptoms come chiefly if not entirely from lesions that are mistaken for diseased gallbladders, in whom the operation of cholecystectomy fails to give the expected relief. It is perhaps not sufficiently appreciated that many common conditions are often confused with gallbladder disease, particularly with the less severe forms of cholecystitis, and that operations are therefore unwisely performed on the biliary tract with necessarily a large percentage of failures, to relieve the patient of symptoms. Some of the most common of these conditions are diseases of the spine, especially osteo-arthritis, chronic constipation, surgical diseases of the right kidney and urinary tract, and duodenal ulcer.

When a decision has finally been reached to perform an operation on the biliary tract in a patient with comparatively mild symptoms of cholecystitis, the surgeon, if he finds little evidence of a pathologic change at the operation, is likely to try to find solace and justification for the removal of the gallbladder in the microscopic examination of the organ. Unfortunately, however, this examination is unlikely to be of much help in just those cases in which the help may be most needed. It is well known, for example, that there is practically no agreement among pathologists as to what constitutes a normal gallbladder. This is especially true after middle life, the period in which most patients present themselves for operation for the condition. It is rare, therefore, for a gallbladder to be pronounced normal on the basis of a microscopic examination.

With these considerations, it should not seem strange that statistics in general have shown that the best results have followed those operations which have been performed in cases not of early or minimal pathologic changes but rather in those associated with relatively advanced changes. The presence of calculi usually

implies a condition of relatively advanced pathologic change. Regardless of the exact origin of stones in the biliary tract, their presence necessarily implies a more advanced state of the process that caused them than the beginning of the process, and under no circumstances can they be regarded as a normal finding, no matter whether their origin was an infection or merely a disturbed state of metabolism. Moreover, it can scarcely be denied that the stones themselves often produce severe symptoms by blocking the ducts or by acting like foreign bodies in maintaining an infection. On the other hand, in the cases of most advanced pathologic changes the results are not likely to be so good because in such cases serious and usually irreparable damage has usually occurred in other important organs, notably the liver and pancreas. Again also the question of overlooked stones in the ducts arises. However, it should not be understood that a satisfactory relief from symptoms is never to be expected in a patient with minimal changes; for, as the analysis to be given will show, even in such cases a satisfactory result may be obtained in the majority of instances provided reasonable care has been exercised to exclude other sources of the patient's complaints.

I should like, therefore, to review certain features based on a study of 161 patients who were operated on at the Barnes Hospital but who had no stones, except in the cases of seventeen who had a combination of cholesterosis with stone. The latter cases were added because by some the conditions of cholesterosis and of cholesterol stones are considered to be expressions of a disturbed metabolism rather than of a definite disease of the gallbladder. All the patients who comprised this study had had a cholecystectomy more than a year before they were reexamined to determine the results.

The 161 patients whose condition was ascertained more than a year after operation were classified, according to pathologic lesions, as follows: minimal lesion, fifty-seven; cholesterosis without stone, thirty-one; chronic catarrhal cholecystitis, fifty-one; chronic fibrous cholecystitis, five; cholesterosis with stone, seventeen.

The term minimal lesion was assigned to those cases in which the gallbladder wall was not greatly thickened, the organ contained concentrated bile, and on microscopic examination there were a few lymphocytes in the wall. A diagnosis of cholesterosis was made when the mucosa of the gallbladder contained the yellowish plaques that are characteristic of lipid deposits. Chronic catarrhal cholecystitis was said to be present when there was edema of the mucosa, a greater infiltration of lymphocytes than in the minimal lesion and some muscular thickening. Chronic fibrous cholecystitis was the term applied to those gallbladders with markedly thickened walls, cuboidal epithelium that often is absent in places, and diverticular crypts. This type of lesion is almost always accompanied by biliary calculi.

The ultimate results in those cases in which no stones were present showed only 60 per cent of patients who considered themselves well. There was an equal number of gallbladders which had a few adhesions and of those which had many adhesions. In the class listed as greatly improved nearly three times as many patients showed only a few adhesions around the gallbladder. On the other hand, all of the seventeen patients with cholesterosis and stone showed either marked improvement or complete recovery from their symptoms.

Of perhaps greater importance and of greater interest is the fact that in 153 cases of this series it was possible to compare the results in those patients who gave a definite history of biliary colic with those who did not have such a history. Of the stoneless cases only 33 per cent gave a history of biliary colic, but 76 per cent of these patients considered themselves well or improved. On the other hand, only 58 per cent of those without biliary colic were well or improved. Moreover, 82 per cent of the patients with cholesterosis and stone gave a history of biliary colic and all were relieved. Again, although the remaining 18 per cent of the cases of cholesterosis with stone did not give a history of biliary colic, nevertheless they were all improved. The importance of stones in the production of symptoms is therefore again emphasized.

In an attempt to correlate the importance of the pathologic changes to the prognosis after cholecystectomy, table 1 was arranged.

TABLE 1.—Importance of Pathologic Changes to Prognosis After Cholecystectomy

	Well	Im- proved	Unim- proved	Postopera- tive Death	Total
Minimal lesion.....	11	22	21	3	57
Cholesterosis.....	14	2	14	1	31
Chronic catarrhal cholecystitis..	18	16	13	4	51
Chronic fibrous cholecystitis....	2	3	0	0	5
Cholesterosis with stone.....	6	11	0	0	17
	51, or 31.7%	54, or 33.5%			161

Table 1 illustrates two points in a striking manner. One is that, although only a small proportion of the patients were relieved of all their complaints, nevertheless about 65 per cent considered themselves improved. This point indicates that there is no justification for an undue pessimism concerning the results of operation on the stoneless gallbladder, despite the fact that the results are far from satisfactory. In this particular group of cases the postoperative mortality was excessively high; in fact, far higher than in our total series of cholecystectomy performed for conditions with and without stones. For the last five years our total operative mortality for cholecystectomy has ranged around 1 per cent. For a period of two years the mortality stayed at only 0.4 per cent. All patients who died in the hospital after operation are considered as postoperative deaths. Actually, however, in the majority of instances the operation probably had little or nothing to do with causing the death. The fact that the mortality is so high in the stoneless cases is found to be due on closer analysis largely to faulty diagnosis; that is to say, many of these deaths were due to general constitutional disorders of which the suspected gallbladder disease proved to be only an insignificant detail. Included in the category of constitutional disorders was one case of a blood stream infection and several other cases of primary hepatic disease. Most of the patients who died probably should not have been subjected to operation at all. This consideration is a matter of great importance because not only does it emphasize the necessity of a complete inventory of the patient who happens to have some evidence of gallbladder disease, but it also indicates that, as a rule, a primary hepatic disease (cirrhosis, toxic hepatitis, and the like) is not favorably influenced by cholecystectomy even when the gallbladder presents definite pathologic changes. Our rule now is usually not to operate on a patient's gallbladder merely

because he presents some evidence of cholecystic disease unless, after a thorough and complete examination, we can satisfy ourselves that probably the symptoms are coming from that organ, at least to a major degree.

Another angle from which this study has been made has been to attempt to correlate the cholecystographic examinations with the ultimate results in cases of the stoneless gallbladder. Of the 161 cases that have been made the basis of this whole study, for various reasons only 114 are available for a particular investigation of the correlation of the cholecystographic response with the ultimate postoperative results. These are presented in table 2.

TABLE 2.—Cholecystogram and Prognosis: 114 Cases

Type of Cholecystographic Response	Total	Clinical Result			Percentage Well or Improved
		Well	Im- proved	Unim- proved Postopera- tive Death	
Normal gallbladder..	10	5	1	4	60
Deformed shadow...	8	4	2	2	75
Faint shadow.....	75	22	22	25	59
No shadow.....	21	6	7	5	62
	114	37	32	39	60

Certain rather astonishing results have been obtained from this particular study. It will be seen, for example, that the total percentage of well or improved patients, which is 60, is about the same as the percentage that showed a faint shadow or a shadow which was designated as being normal. Some discussion is needed to clarify these points. The ten patients who were operated on in spite of a normal cholecystographic response had their operations because it was felt that the symptoms warranted the operation in spite of the negative roentgen examinations. The series of ten cases of this sort is, of course, far too small from which to draw any sweeping conclusions. Moreover, since six of these patients considered themselves either well or improved after operation, our own inclination is to assume that probably the removal of the gallbladder had little or nothing to do with the relief of the symptoms. Our routine procedure is to remove the appendix also whenever a cholecystectomy is performed. It is within the range of possibility, therefore, that the removal of a diseased appendix was perhaps more responsible for the relief of symptoms in these cases than the removal of a normal gallbladder.

Previous studies have shown that at our hands a gallbladder that appears normal on cholecystographic examination rarely shows any pathologic changes other than those which we have described as minimal in this article. The question of faintness of shadow is an old stumbling block. From the beginning of our experiments with cholecystography as well as those of others it has been recognized that faintness of shadow constitutes a great difficulty in diagnosis of cholecystic disease. The fact that only 62 per cent of those patients who had no shadow were relieved of their symptoms by cholecystectomy may occasion some astonishment because ordinarily others as well as ourselves have interpreted the failure of a shadow as a definite indication of demonstrable disease of the gallbladder in practically all instances, provided the technic has been satisfactorily performed. The fact that in this series only 62 per cent of such patients were relieved of their symptoms after cholecystectomy in our opinion merely indicates again the frequency with which the chief symptoms of which a patient complains are ascribed to the gallbladder

merely because that shows some evidence of disease. It is not a reflection on the value of cholecystography as a means of demonstrating a disturbed function of the gallbladder but rather it constitutes a reflection of our failure to assess properly the different complaints of the patient. In other words this finding reemphasizes the necessity of a complete and thorough search in other parts of the body for the causes of symptoms that may be thought to be due to the gallbladder, especially when those symptoms are not severe.

SUMMARY

This study emphasizes the point that from the standpoint of satisfactory results the symptom of pain, particularly the typical biliary colic, is an important feature. In the absence of severe pain the beneficial results to be obtained by cholecystectomy in cases of a stoneless gallbladder are likely to be unsatisfactory in approximately 40 per cent. There seems at present to be little justification for the subjection to operation of patients who have only the early beginnings of cholecystic disease, unless one is interested in the prevention of complications. At any rate, the evidence indicates that if one operates on such patients the results will be far from satisfactory in almost one half of the cases. In this article no particular mention has been made of other features of cholecystic disease, such as flatulent dyspepsia. It will be apparent, however, from the remarks already made that symptoms other than pain which are commonly associated with gallbladder disease are much less likely to disappear after cholecystectomy than is pain itself, unless the changes in the organ are definite and marked. The determination of how much a patient's symptoms are due to the gallbladder in a case of minimal disease of that organ is extremely difficult. Many of these patients are undoubtedly on the borderline between purely functional and anatomic disorders that produce disturbances of function. In order to arrive at a satisfactory incrimination of the gallbladder it is necessary to examine the patient thoroughly with reference to the possibility of other sources of the complaints; and so far as the gallbladder itself is concerned it is necessary not only to take a very careful clinical history but also to resort to various special methods of examination. Even after the presence of cholecystic disease is demonstrated in the anatomic sense, however, it is still difficult to satisfy oneself that the function of the organ is sufficiently disturbed by those pathologic changes to cause the symptoms of which the patient complains. The presence of calculi and the history of typical biliary colic greatly increase the chance of a satisfactory result after cholecystectomy.

Introduction of Lumbar Puncture.—In the year 1891, and in a quiet way, came an experiment which slowly led to the most astounding progress in our knowledge of nervous disease and of its diagnosis, differentiation and treatment. No event in the history of neurology has brought so many assets as has the introduction of lumbar puncture. Quincke of Magdeburg conceived that he might relieve the symptoms of hydrocephalus by draining the cerebrospinal fluid. Six years previously Corning in America had drained the fluid for the treatment of tuberculous meningitis, but Quincke was the first to make his work known throughout the world. The discovery of changes indicative or characteristic of certain diseases in this hitherto unimportant fluid soon followed, and lumbar puncture has become a routine in diagnosis and treatment.—Collier, James: The Harveian Oration on "Inventions and the Outlook in Neurology," *Brit. M. J.* 2:707 (Oct. 20) 1934.

THE APPLIED PHYSIOLOGY OF THE
EXTRAHEPATIC BILIARY TRACT

A. C. IVY, PH.D., M.D.

AND

G. S. BERGH, M.D.

CHICAGO

Since an epoch in the advance of knowledge of the physiology and functional pathology of the biliary tract has been witnessed during the past decade, it is appropriate to outline the present state of information concerning it.

The gallbladder manifests, like the intestine, three types of activity: absorption, secretion and motor activity.¹

ABSORPTION OR CONCENTRATION

In the process of absorption, the gallbladder concentrates the hepatic bile that enters it from four to ten times. Chiefly water and certain inorganic constituents are absorbed. In the process of absorption the bile, which is alkaline as it leaves the liver, is slightly acidified. The bile acids render the fats and cholesterol soluble at the acid reaction of gallbladder bile.

The concentrating function of the gallbladder renders it a reservoir of small volume but large capacity. In the fasting human being or dog it may store the entire twelve or twenty-four hour output of hepatic bile. This is the reason why dogs without a gallbladder become jaundiced sooner after complete common duct obstruction than dogs with a gallbladder.²

The bile ducts of animals possessing a gallbladder do not concentrate to a significant extent.³ The bile in the obstructed duct, in the absence of the gallbladder, may look considerably darker than hepatic bile for the first day or so, but this is said to be due to a change of bilirubin to biliverdin.^{3a} If there is any concentration of bile in the obstructed common duct in the absence of the gallbladder, it does not amount to more than two or three times.^{3b}

The acutely inflamed gallbladder mucosa does not concentrate. If the inflammation of the mucosa is "patchy" or if the inflammation is localized to the serosa or muscularis, the gallbladder may concentrate. The acutely inflamed gallbladder does not evacuate. After the acute inflammation has subsided, the gallbladder may again concentrate and evacuate. However, if fibrosis results, concentration does not occur, or is slight.⁴

Caylor and Bollman⁵ found that the gallbladder which has hypertrophic rugae with papillomas concentrates exceedingly well. We⁶ can verify this for dogs. Such gallbladders, of course, visualize well, until inflammation occurs. Hyperplasia of the rugae and lymphoid

tissue of the gallbladder may be produced in the dog by biliary stasis⁶ caused by stricture of the common duct or reversed loops of the duodenum. Thus, a hypertonic sphincter of Oddi or abnormal duodenal motility may cause stasis and hypertrophy of the gallbladder mucosa.

Cholesterosis of the gallbladder ("strawberry gallbladder") is a condition characterized by lipid deposits in the mucosa of the organ. Its pathogenesis is not well understood, but a similar condition has been obtained experimentally in rabbits by producing low grade inflammatory changes in the gallbladder wall and at the same time feeding cholesterol. Cholesterosis does not interfere with the concentrating activity or emptying of the gallbladder unless associated with a moderate or severe cholecystitis.⁷

SECRETION

The gallbladder secretes normally a mucoid fluid. The normal rate is not known, but in human cases of cystic duct obstruction with a gallbladder fistula, 20 cc. for each twenty-four hours has been collected.⁸ When the gallbladder is acutely inflamed, a considerable quantity of limpid, sometimes blood-tinged, fluid is formed by the mucosa.⁹

The ducts secrete a colorless slightly viscous substance, particularly when obstructed.

When the common duct is obstructed for twelve or fourteen days with a normal gallbladder in place, green fluid, or a "green system," is found in the ducts. When the common duct is obstructed for twelve or fourteen days with the gallbladder out or functionless, a white fluid, or a "white" system, is found. This is the "white bile" that the surgeon finds not infrequently.^{3a}

"White bile" or lightly pigmented bile is found and can be produced experimentally under the following conditions: (a) common duct obstruction with a functionless gallbladder; (b) when liver secretes against pressure in the absence of total obstruction; (c) toxic hepatitis (chloroform, and the like); (d) high grade ascending infections or hematogenic hepatitis. In infectious febrile diseases such as pneumonia, bile output is decreased, but a "white bile" is not secreted unless there is an associated hepatitis.

The "white bile" of the gravest concern to surgeons is associated with toxic or a generalized hepatitis. Here one must treat the hepatitis, whether due to obstruction or other causes. If the surgeon finds no obstruction, the patient should not have been operated on; but the differential diagnosis is not always easy. There is, of course, a high grade dye retention and icterus in all "white bile" cases.

Clinical experience indicates that dextrose may be used effectively in these cases. Dextrose favors the activity of liver cells and also the reduction of coagulation time of the blood.¹⁰ Calcium chloride is also used by some clinicians, particularly in the presence of a hemorrhagic tendency. The evidence indicates that even in the bleeding cases calcium affects some tissue, probably the liver, other than the blood.¹¹ Bile salts should probably not be used to start a flow of pigmented bile,

From the Department of Physiology and Pharmacology, Northwestern University Medical School.

A consideration of cholelithiasis and reflex symptomatology is intentionally omitted from this discussion.

since, according to Adlersberg,¹² dehydrocholic acid decreases the rate of elimination of bilirubin and dyes from the blood into the bile.

MOTOR ACTIVITY OF GALLBLADDER

The motor activity of the gallbladder is of two types first, rhythmic tonus changes amounting to from 1 to 3 cm of bile pressure, which may be augmented in rate and amplitude by any mild adequate stimulation, and, second, a tonic contraction of the musculature of the gallbladder as a whole. The gallbladder of the dog by contracting may exert a pressure of from 20 to 30 cm of bile.¹ The force of contraction of the human gallbladder has not been measured, but it has been seen by direct vision to contract and evacuate.¹ It is interesting that stones located in a group in the fundus of the gallbladder may line up in a column of twos after the ingestion of a fatty meal.¹³

It is obviously significant that the power of the normal gallbladder to contract is not greater than the secretory pressure of bile.

The chief stimulus of gallbladder contraction thus far discovered is the hormone cholecystokinin. The stimulation of nerves has never been observed to have more than a slight and temporary effect on gallbladder evacuation.¹

The hormone may be extracted from the duodenal mucosa and, when injected intravenously, causes a more or less prolonged contraction of the gallbladder with evacuation. It has been demonstrated to operate physiologically by cross-circulation and transplantation experiments in the dog and by blood transfusion experiments in man.¹

The most effective excitants of hormone production are acids and fats acting in the upper part of the intestine. All fats are effective, but egg yolk and cream appear to be the most active. Proteins, particularly meat, rank next, and carbohydrates have no action.

The action of many drugs on the musculature of the gallbladder has been studied. In our hands, cholecystokinin has proved to be the most powerful gallbladder motor excitant known and produces no side actions such as a fall or rise in blood pressure.

Atropine relaxes the gallbladder but does not abolish the action of cholecystokinin. Morphine, when effective, increases the tonus rhythm of the gallbladder. Pilocarpine may cause some expulsion of bile from the gallbladder into the ducts, but it does not cause evacuation, owing to its augmentation of sphincteric and duodenal tone. Solution of pituitary after a latent period of ten or fifteen minutes causes the gallbladder to contract and frequently to evacuate from one fourth to one half of its contents. However, solution of pituitary is not as effective as egg yolk and fat.¹

Surgical operations such as gastro-enterostomy, gastric resection, and pyloroplasty do not decrease the efficacy of egg yolk in provoking gallbladder evacuation.¹⁴ However, the injection of egg yolk into the mid or lower part of the ileum has no effect on the gallbladder.¹ During the first day or two following operations on the upper part of the abdomen the gallbladder may manifest a rather marked atonic distention.¹⁴

SPHINCTER OF ODDI

Whether or not the gallbladder will evacuate when stimulated depends on the tone of the sphincter of Oddi or duodenum, or the intramural resistance offered to the flow of bile from the common duct into the lumen of the duodenum. (We shall hereafter designate the intramural resistance as being due solely to the sphincter of Oddi, which is true only in part.)

The sphincter of Oddi can resist up to 75 cm of bile pressure, whereas the maximum expulsive pressure of the normal gallbladder is 30 cm. Hence it is possible for a spastic sphincter or duodenum to prevent gallbladder evacuation.

In human subjects it has been shown that, if the sphincter is spastic, biliary colic may be produced by exciting the gallbladder to contract. Magnesium sulphate introduced into the duodenum will relieve the pain, and dark bile will be obtained.¹⁵ This condition has been called "hypertonic dyskinesia" by Westphal,¹⁶ "cholepathia spastica" by Schmieden,¹⁷ "spastic distention" by Newman,¹⁸ "spastic dysfunction" by Lyon¹⁹ and "physiologic block" by Smithies.²⁰

What is the present status of the Doyon-Meltzer concept, which maintains that when the gallbladder contracts, the sphincter relaxes? It can be stated that the evidence obtained by the best methods supports this concept.¹ There is evidence showing that, when the sphincter contracts, the gallbladder fills, as might be expected. Whether this is due to a reciprocal nervous mechanism or is only passive is not settled. That the literature is not in agreement is not surprising when one views the intricacy of the possible mechanisms and recalls that many years were required to clear up the stomach-pyloric sphincter relationship.

The fact that the sphincter of Oddi becomes incompetent soon after removal of the gallbladder shows that the gallbladder has some functional relation to the sphincter. Later in most instances the sphincter becomes sufficiently competent to cause the ducts to dilate. Section of the sphincter prevents dilatation.²¹ Certain other facts pertaining to the physiology and functional pathology of the sphincter of Oddi may be summarized as follows: (a) Any procedure that increases the muscular tone of the duodenum inhibits the flow of bile into the duodenum.²² (b) Any procedure that decreases the tone of the duodenum favors the flow of bile. (c) Chemical irritation of the duodenum delays gallbladder evacuation. (d) Atropine favors the flow of bile into the duodenum and pilocarpine stops the flow of bile. (e) Morphine tends to inhibit the flow of bile into the duodenum, owing to its effect of increasing the tone of the circular muscle of the duodenum. (f) magnesium sulphate, magnesium oxide and sodium sulphate favor the flow of bile. (g) In some patients having cholecystitis or duodenal ulcer the sphincter may be hypertrophied.²³ (h) It is reported that some time

after cholecystectomy the sphincter may become competent or possibly undergo hypertrophy.²⁴ (i) In animals without a gallbladder the sphincter resistance is less than in animals having a gallbladder.²¹

It is known both from comparative physiology and by actual experiment that one of the functions of the sphincter is to fill the gallbladder, another function being possibly to prevent regurgitation of contents and transmission of pressure from the duodenum to the common duct.

On weighing the evidence pertaining to the relationship between the gallbladder and the sphincter of Oddi or the choledochoduodenal mechanism, we are convinced that the gallbladder and the sphincter constitute a functional unit. This concept was implied by Oddi in 1887 and was clearly stated by Doyon in 1894. This concept directly implies that serious consideration must be given to the sphincter of Oddi or the choledochoduodenal mechanism in order for the functional pathologic changes and the therapy of biliary tract disease to be understood.

TYPES OF EVACUATION

Those investigators who have devoted considerable time to the detailed study of the mode of gallbladder evacuation consider the gallbladder and sphincter of Oddi as a functional unit. This is exemplified in the types of evacuation that Boyden²⁵ has described for "normal" subjects and in the types of motor dysfunction described by Westphal and others.

Boyden,²⁵ who has studied by a quantitative method more than 100 "normal" human subjects, recognizes three types of gallbladder response to a fat meal. In the first type, a primary relaxation of the gallbladder results with what appears to be a closure of the sphincter. Only a temporary delay in emptying occurs. This type is relatively rare. In the second type, which is more common, contraction and evacuation start quickly with simultaneous relaxation of the sphincter, and evacuation occurs rapidly. This comprises the larger group of subjects, evacuation being complete (95 per cent) in two hours. In the third type, evacuation starts but, after an interval, stops. Then, filling of the gallbladder occurs. Further, evacuation occurs in successive phases. Boyden thinks that in this type the sphincter is primarily concerned in stopping the evacuation and starting the filling, since the speed of the initial evacuation is normal.

Westphal²⁶ has described two major types of motor dysfunction of the biliary passages.

I. Hyperkinetic.

(a) Hypermotile: Increased motility of gallbladder and ampulla with rapid emptying.

(b) Hypertonic: Contraction of the gallbladder against spasm of the sphincter with spastic distention and colicky pain.

II. Atonic: Relaxation or atony of the gallbladder with spasm of the sphincter of the papilla causing atonic distention of the gallbladder with mild continuous "heavy," aching sensation.

Westphal^{26b} and Kalk²⁷ report that in from 10 to 20 per cent of patients who complain of biliary tract dis-

tress the distress is due to a motor dysfunction of the gallbladder and sphincter. These and other authors¹⁷ including Aschoff²⁸ attribute the so-called stasis gallbladder to a functional motor disturbance. Newman¹⁸ has cautioned against the division of motor dysfunctions into hard and fast entities and, we believe, properly so. However, we believe that the concept is sound from a physiologic point of view.

THERAPEUTIC CONSIDERATIONS

Prevention of gallbladder disease may be aided by the daily evacuation of the viscous by the appropriate intake of fat. This applies particularly to the gallbladder that evacuates slowly and incompletely but without causing symptoms. Such prophylaxis should be a part of antepartum care.

In acute biliary tract disease not demanding immediate operation, the employment of the physiologic principle of sedation has been and is effectively employed. Foods such as fats, meats and acid fruit juices which excite activity should be withheld. Magnesium sulphate or magnesium oxide, because of the relaxing effect of magnesium on the sphincter, may be used. Atropine or belladonna is indicated for the same reason. The advisability of using bile salts or dehydrocholic acid, in order to promote the formation of bile in these cases, is to be seriously questioned. If the obstruction is complete, or almost so, the pain or distress will be increased. This would be true even with the gallbladder out, since distention of the ducts causes distress.

If the sphincter or duodenum is hypertonic or irritable, the procedures that decrease intramural resistance are indicated. Fat (egg yolk, milk and cream) tends to decrease the tonicity of the duodenum as well as the stomach, but the amount to be used will depend on the condition of the gallbladder. If the gallbladder is atonic, fat will favor evacuation; but if the gallbladder is irritable, the fat intake will have to be adjusted to the "tolerance" of the patient.

It must be recognized, however, that there are patients having chronic cholecystitis whose gallbladders visualize poorly with or without one or more large stones present (by large we mean capable of causing impaction of but not capable of passage through the cystic duct) in whom fatty meals or "mayonnaise dressing" or fruits rich in organic acids, cause trouble; that is, these excitants in excess produce right hypochondrial distress, stitching pains or soreness in the region of the scapula, or even colic. In those patients who refuse operation, excitant foods must be reduced to meet the patient's tolerance. The "tolerance" can be ascertained only after careful dietary experimentation, a cooperative patient of fair intelligence being prerequisite. The gallbladder excitatory foodstuffs should not be eliminated from the diet entirely. Too much of the excitants will irritate the gallbladder, but absence of the excitants will cause stasis, and stasis must be avoided. These are the patients who, refusing operation and not being helped by the physician, we believe go to the drug store and purchase "pills" that contain a cathartic and bile salts. So far as is known, bile salts only increase the fluid volume of the bile, the total output of bilirubin and other biliary constituents being unaltered or slightly diminished. It is rational to believe that bile salts have a place in the therapy of chronic but not of acute biliary tract disease.

CHOLECYSTOSTOMY

It is well known that unless great care is taken, in the dog cholecystostomy always leads to infection of the biliary passages in from two to three weeks. Several reports are available in which cholecystography was done after cholecystostomy in man. Graham²⁹ found nonvisualization in all but one. Spurling and Whitaker³⁰ in twelve cases failed to find a normal cholecystogram. Fleming³¹ studied thirty-six cases, one showing a normal shadow, six visualizing but having impaired function, and twenty-nine failing to visualize. The lack of preoperative cholecystograms makes it impossible in these cases to evaluate the effect of cholecystostomy. The evidence is strongly presumptive, however, that the gallbladder is not benefited by drainage. If the mucosa is not permanently damaged, the scarring incident to drainage may interfere with normal emptying.

CHOLECYSTECTOMY

It is now generally recognized that cholecystectomy is definitely indicated in patients with multiple small stones, and in cases of nonvisualization with a high grade chronic cholecystitis. If the gallbladder is so permanently injured that it does not visualize, from the physiologic point of view, a functional cholecystectomy has already been performed, and if it is harboring infection or stones no harm or change can result from cholecystectomy, if postoperative adhesions and surgical accidents are not considered.

As already pointed out, the removal of a gallbladder which concentrates leads to physiologic and anatomic changes in the biliary passages. For this reason, if for no other, the gallbladder cannot be viewed as a vestigial organ to be removed without adequate and justifiable reason. This statement will not stand unequivocally, however, unless it is supported by evidence showing that actual injury may result as a consequence of either an incompetent sphincter or a competent sphincter with a dilated duct. Unless it can be shown that cholecystectomy has actually a harmful effect, the operation will always be performed in borderline cases in which the gallbladder is suspected of being at fault.

In the dog, a cholecystoduodenostomy or a cholecystogastrostomy with or without gastro-enterostomy leads in the course of several months to an ascending biliary tract infection and hepatitis. The same is true in man. Apparently a normal sphincter of Oddi serves as a barrier against ascending hepatitis. Thus, following cholecystectomy, the presence of an incompetent sphincter favors regurgitation, or the presence of a competent sphincter and dilated ducts may favor stasis. Theoretically, infection might occur in either case unless the bile flow was always sufficiently copious to prevent regurgitation or stasis. In this connection, we have often wondered whether those patients (adhesion free) who have distress after cholecystectomy are (a) those who have an incompetent sphincter, (b) those who have a competent sphincter with dilation of the ducts, or (c) those who had a hypertonic or hypertrophic sphincter prior to the cholecystectomy. (Of course, the presence of a chronic infection of the ampulla and ducts must also be considered.) The only information that

we have been able to find on this question is as follows: Zander³² reports that spastic contractions of the sphincter of Oddi may occur after cholecystectomy. Rehn and Hoseman,³³ in a series of 215 cases, removed twenty-five stone-free gallbladders; of the twenty-five, seven presented symptoms accountable for by a spastic or hypertrophic sphincter. Westphal³⁴ reports that residua remain in from 20 to 30 per cent of cholecystectomized patients. On duodenal drainage in these patients and after the instillation of oil, he obtains more highly pigmented stasis bile. As Giordano and Mann³⁵ and also Westphal³⁶ have pointed out, a spasm or hypertonic or hypertrophied sphincter may obstruct not only the outflow of bile but also of pancreatic juice in those patients (20 per cent) whose duct of Wirsung opens into the ampulla at a high level.

It should be pointed out that a patient having a hypertonic or hypertrophic sphincter may obtain temporary relief following a cholecystectomy, owing to the preliminary paresis of the sphincter that always results. But on recovery from the temporary paresis, the hypertonicity of the sphincter may recur and produce symptoms. It may or may not be possible to manage such patients medically. Whether section or dilatation of the sphincter, or choledochoduodenostomy or cholecystoduodenostomy with or without gastro-enterostomy is the operation of choice when medical management fails, we believe remains an experimental and clinical problem. Of course, if the ampulla, common duct or intrahepatic ducts are infected, the conditions are altered, and T tube drainage is, we believe, a rational procedure. This is of physiologic interest because the presence of inflammation in the crypts of the ampulla may increase the irritability of the sphincter and a relief of the inflammation by drainage may decrease the irritability of the sphincter.

What are the observed facts pertaining to the harmful effects of cholecystectomy? It is known that the cholecystectomized dog and man may live a long time in apparently good health. This may or may not be significant, because the factor of safety in digestion and in the liver is large. In man there is no information on the effect of cholecystectomy on the liver except that of Rost,³⁴ which is unsatisfactory. Without controls he thought that cholecystectomy caused hepatitis. In the dog there is one report³⁵ in which a slight hepatitis was found after cholecystectomy and another³⁶ in which hepatitis was not found. Rost³⁴ reports that pancreatic secretion and bile formation are decreased. In man, McClure³⁷ reports that in cases with cholecystectomy the pancreatic secretion is diminished, but no control studies were made before the operation.

Hence the evidence at hand is inadequate to warrant the statement that actual damage is done the patient by removing a gallbladder that visualizes and empties. The fact, however, that physiologic and anatomic changes do result following the removal of such a gallbladder should deter the surgeon at least until medical control has been tried. This fact also condemns the idea of prophylactic removal of the gallbladder or its

AND
P. J. MORRISON, B.A.
PHILADELPHIA

It is only slightly more than a decade ago that Rous and McMaster¹ published their observations on gallbladder function. Besides extending knowledge their work gave quantitative confirmation of much that had been done previously. Since then a great deal has been accomplished, as can be seen from the review recently published by Ivy;² but as yet knowledge of the normal and pathologic physiology of biliary function is incomplete. The excretory, secretory and absorptive functions of the liver and gallbladder and their associated ducts in health and in disease must of course be intimately correlated with the chemistry of the bile. It is with these aspects of function that we, as well as numerous other investigators, have concerned ourselves.

Under normal conditions the hepatic bile of the dog maintains a fairly constant chemical composition (figs. 1 and 2).³ Although this is very likely true for man also, we cannot make this statement definitely, for we have only been able to study human hepatic bile over long periods in patients who presented surgical lesions of the biliary tract when first seen. However, hepatic bile obtained from the common duct of patients when complete or nearly complete hepatic restitution had

Fig. 1.—Normal dog bile.

taken place is, with the exception of the cholesterol concentration, similar to normal dog's hepatic bile in its composition. In human hepatic bile the concentration of cholesterol is significantly higher than it is in dog's bile.

When normal hepatic bile of dog or man is received in a normally functioning gallbladder, certain definite changes occur. Water is absorbed at a rate as high,

in the dog, as 6.75 cc. per hour.⁴ The chloride and bicarbonate are rapidly absorbed, so that there is a marked decrease of these substances both in absolute amount and in concentration in normal gallbladder bile. The concentrations of cholesterol and of bilirubin increase and there are no quantitative data which indicate that under normal conditions these substances are either absorbed or secreted in the gallbladder. The calcium and bile salts are concentrated, but small amounts of both these substances are absorbed. The bile normally becomes more acid during this process of selective concentration and absorption.

Fig. 2.—Normal human bile.

The part that such a mechanism plays in the body economy has been a much debated subject. The substances except water that are known to be absorbed from the normal gallbladder bile and returned to the blood are absorbed only in insignificant amounts, and there is no available evidence which indicates that any important substance is secreted by the normal gallbladder into the bile.

The fact that certain species are born without a gallbladder and that man can live a normal life span in apparently perfect health after its removal is, however, not in itself evidence that the normal viscus is unimportant in those species in which it is found. The data of McMaster,⁵ who found that the rat, which has no gallbladder, secretes hepatic bile that contains eight times as much bilirubin as is found in the hepatic bile of the mouse, which has a gallbladder, and of Boyden,⁶ who found that a cat in which the gallbladder was congenitally absent secreted bile with a bilirubin concentration 2.2 times as high as a cat whose gallbladder was present, are of interest in that they demonstrate an ability of the liver under such circumstances to secrete a more concentrated bile.

Ivy,² who has reviewed the available data carefully, has concluded that "the gallbladder is a factor of safety in physiological economy." If this is true, and we believe that it is, the normal organ should not be removed with the same impunity that one would remove a so-called chronically diseased appendix.

When the gallbladder becomes damaged by trauma or infection, certain significant changes occur in the composition of gallbladder bile (figs. 3 and 4). There may result merely a retardation in the rate of absorption and concentration. From this simple change one may find all types of perversion of function until, in the

severely damaged gallbladder, fluid flows into its lumen instead of being absorbed from it, and other substances previously absorbed may be secreted into it, while substances that were only concentrated may be absorbed.⁷

For purposes of discussion we have divided the patients whose gallbladder bile we have studied into three groups: (1) patients having chronic cholecystitis without calculi, (2) patients having chronic cholecystitis

The data we have collected from bile specimens obtained from gallbladders falling in these groups indicate that with increasing impairment of function there was generally an increasing tendency for the bile to become more dilute in some materials and more concentrated in others. This may be due to retardation of water and solute absorption, to dilution of the hepatic bile after the gallbladder receives it, or to the addition of substances as fluid flows into the gallbladder lumen. In general it may be said that the concentrations of calcium and of bile salt show a progressive decrease with increasing severity of damage, the latter being

with calculi and (3) patients having abnormal calcium deposits in the gallbladder wall or lumen.

In patients with proved chronic cholecystitis without calculi the change in the chemical composition of the bile is often not very great, although definite exceptions were found. In most of the specimens of bile from a chronically diseased noncalculous gallbladder that we have studied we have found evidence of concentration of calcium or bile salt, or both, whether or not the gallbladder was visualized after the administration of tetraiodophenolphthalein sodium. A few of the representative data are given in table 1.

Of the patients with chronic cholecystitis with calculi, two general types present themselves (table 2): (A) Patients whose gallbladders are visualized after the administration of tetraiodophenolphthalein sodium. In these evidence of the concentration of calcium and to

measured by evidence obtained from cholecystographic studies. The larger number of low values for both calcium and bile salts were obtained in the group having the most severely damaged gallbladders. The chloride concentrations, on the other hand, show a progressive tendency to increase in concentration with increasing

a lesser degree of bile salts was also as a rule obtainable. (B) Those whose gallbladders were not visualized after the administration of the dye. Although evidences of the concentration of calcium and at times of bile salts were found, the data as a rule show a greater deviation from the normal than do those of the previous groups.

⁷ In all references in this paper to the determination of bile salts the analyses were made by the Gregory-Pascoe method.²² Both free and conjugated cholic acids respond with a characteristic color reaction, although desoxycholic and perhaps other naturally occurring bile acids cannot be determined by this method. Experiments now being conducted in this laboratory suggest that, even when the typical Gregory-Pascoe reaction is not obtained, some free or conjugated bile acids may be present but the reaction may be masked.

evidence of a perversion of function, the highest values being found in the group having chronic cholecystitis with calculi and in which the gallbladder did not visualize after the administration of tetraiodophenolphthalein sodium.

The cholesterol concentration varied greatly and in the data given here appears to vary as a rule with the bile salt concentration; i. e., the lowest value for cholesterol was found when no bile salt was demonstrable, and many of the highest values for cholesterol were found in bile having the highest bile salt concentration.

However, there were exceptions to the latter, and it was not possible to show a definite linear relationship between the variations in the two constituents. The evidence strongly suggests that cholesterol may be secreted into the gallbladder bile in at least some of the damaged gallbladders, because the concentration of cholesterol in some instances was considerably higher than in normal hepatic bile, and there was at times no evidence of the concentration of other constituents normally concentrated in the gallbladder bile. This is at least partially in agreement with the data reported by Elman and Graham.⁸ Data that we have obtained in the dog would appear to corroborate this concept.

The relationship of these changes to the failure of the gallbladder to visualize in cholecystography is of some interest. Frequently the roentgenologist reports the nonvisualized gallbladder as a "nonfunctioning gallbladder," which implies a static condition of the gallbladder wall. In reality the dye in the hepatic bile may be further diluted on reaching the gallbladder by a viscus whose function is perverted, or it may be more rapidly absorbed than it is under normal circumstances. Both of the mechanisms tend to prevent visualization, but they are evidences of a perversion of function which is a dynamic process rather than of loss of function.

In the third group the outstanding feature is the increase in the amount of calcium that may be found in the gallbladder. The gallbladder may be filled with a white fluid "kalkmilch" consisting largely of calcium carbonate, or there may be a gelatinous mass filling the gallbladder in which streaks of this emulsion together with calcium carbonate stones may be found. There may be a single stone obstructing the cystic duct either covered on one side or surrounded by a small or large amount of calcium carbonate (figs. 5 and 6). These lesions have been described and discussed by Willich,⁹ Volkmann¹⁰ and Phemister and his associates.¹¹ In still another type the calcium may be precipitated in the gallbladder wall as described by Jones and Palmer¹² (fig. 7).

With the exception of those showing merely calcification of the gallbladder wall, the condition is generally associated with cystic duct obstruction, but no adequate explanation has been advanced to explain the large amounts of calcium often found in these gallbladders. Several years ago we¹³ called attention to the fact that the increase in the alkalinity of the bile in a damaged gallbladder and the high bicarbonate present in certain specimens of gallbladder bile in disease provided favorable conditions for the precipitation of calcium. If the calcium is secreted by the gallbladder wall in these cases, fluid must enter the gallbladder with it. We have previously reported¹⁴ that in hydrops of the gallbladder the fluid pouring into the lumen of the gallbladder has a calcium concentration of from 5 to 10 mg. per hundred cubic centimeters. This agrees with the data reported by Fowweather and Collinson,¹⁵ who found calcium concentrations of from 2.8 to 15 mg.

per hundred cubic centimeters in "white bile" from the human gallbladder. It may be that there are periods of increased damage of the wall when fluids pour in and periods of a return to more normal function when fluids are absorbed, the calcium remaining behind. Murphy and Bollman¹⁶ have reported evidence which demonstrates that the gallbladder may again concentrate after recovery from acute cholecystitis.

The low bile salt concentrations frequently found in bile from a damaged gallbladder and previously reported by Rosenthal and Licht,¹⁷ Newman,¹⁸ Andrews, Schoenheimer and Hrdina¹⁹ and by us²⁰ have been used, together with the cholesterol concentration, in obtaining a bile salt-cholesterol ratio. The formation of certain gallstones has been attributed to deviation of this ratio from the normal, the cholesterol precipitating out of the bile when the bile salt concentration falls below a critical level. Newman²¹ has reported that the bile salt-cholesterol ratio normally is about 18, whereas "in bile from gallbladders with faceted stones it is 2.5 and in bile from gallbladders containing calcium pigment stones it is normal. Of the bile salt-cholesterol ratio in cases of cholesterol solitaire stones nothing is known."

TABLE 3.—Bile Salt-Cholesterol Ratio in Various Types of Stones

Ar.....	930	136	6.8	Cholesterol solitaire

In table 3 are given data which demonstrate that the matter is not nearly so simple. Data previously reported in this paper show a wide variation of the bile salt-cholesterol ratio even in noncalculous gallbladders. There is no doubt that bile salts are often completely or nearly completely absorbed from the damaged gallbladder. This may occur, however, without the entire bile cholesterol being precipitated from the bile. Nor can one state that the bile removed from the damaged gallbladder on one occasion may not be markedly changed at a subsequent examination. The perversion of function needs by no means remain static, as the data in table 4 demonstrate. One has no right to conclude that calculi were formed under the conditions of the bile found at operation. The evidence we have collected would seem to demonstrate that the gallbladder bile may be profoundly altered when only a cholesterol solitaire stone is found in the gallbladder, a condition which many believe is purely metabolic in origin. Trauma of the mucosa alone may alter the concentrating activity of the gallbladder to an unusual degree.

We have studied the chemistry of human gallbladder bile removed at operation and the chemistry of the stones found in the same gallbladder. The data are of little significance in that stones of different chemical composition are found bathed in bile of strikingly similar character while stones of the same type are often found in bile whose composition is not similar.

TABLE 4—Gallbladder Bile at Two Stages in the Same Patient

In the acutely inflamed gallbladder with stones in which the cystic duct becomes obstructed, marked changes in the composition of the bile are found long before empyema occurs (table 5). The greatest changes are found in the gallbladder of hydrops, in which the fluid removed has not the faintest visual resemblance to gallbladder bile. The calcium concentrations show a further tendency to decrease, while the chloride concentrations are consistently higher. It is in this type of gallbladder that the bile only rarely contains even a trace of bile salt. Nonprecipitated cholesterol is found

in the fluid contents of the gallbladder even though the bile salts are absent. The rapidity with which such a gallbladder permits bile pigment to be absorbed while the normal gallbladder completely retains this substance is a striking example of the degree of perversion of function that may take place in disease. The acutely inflamed gallbladder pours fluid into its lumen so that even though the cystic duct is open the gallbladder will not be visualized cholecystographically, although later with a subsidence of the inflammation this may be possible.

TABLE 6—Hepatic Bile in Cholangitis

Wi	4.2	427.4	0

We had observed several years ago that, when cholangitis²² occurred in dogs whose hepatic bile was previously normal, the bile salt concentration of the hepatic bile as measured by the Gregory-Pascoe reaction²² decreased markedly. This finding we have now confirmed in man (table 6). The evidence we had obtained led us to state that our data at least suggested that the liver bile was the sole site for the synthesis of bile salts. The calcium levels in hepatic bile from patients

with cholangitis tend to be below the normal hepatic bile level, while the chloride level is in general above the normal level. In these respects the data from both man and dog are in agreement. The cholesterol concentration of hepatic bile increases in cholangitis, and this would appear to be related to the degree of supuration and the exfoliation of mucosal cells.

When the common bile duct becomes obstructed either completely or partially from stone, tumor or cicatricial stenosis, the hepatic bile becomes altered in its composition. The most profound changes occur when the obstruction is complete and the pressure in the bile ducts exceeds the hepatic secretory pressure. The "white bile" found in many of these patients needs little comment. It is present only because the hepatic parenchyma no longer is functioning normally and is the result of the activity of the mucosal cells lining the ductal system.

Fig. 5—Calcium precipitation in the gallbladder lumen, calculus obstructing the cystic duct

The extent of the change in the hepatic bile depends on the extent and the duration of the obstruction, the degree of associated infection and the presence or absence of a normally functioning gallbladder. When the obstruction is complete and there is a coincidental cholangitis together with a severely damaged gallbladder, the changes in the hepatic bile appear early and are most marked.

The most striking finding in the hepatic bile obtained by common duct drainage after the release of a ductal obstruction is the reduction of the bile salt concentration as measured by the Gregory-Pascoe reaction²² (table 7). Greene, Walters and Fredrickson²³ several years ago reported studies on the common duct bile after release of partial and complete obstructions of the common duct.

Although Greene, Walters and Fredrickson found a reduction of the bile salts as measured by the Aldrich-

²² Gregory, R. and Pascoe, T. A. J Biol Chem 83:35 (Jul) 1929.

²³ Greene, C. H., Walters, Waltman, and Fredrickson C. H. J Clin Investigation 9:295 (Oct) 1930.

Bledsoe method, in hepatic bile after ductal obstruction we have found an absence of the bile salts as measured by the Gregory-Paseoe reaction in specimens of hepatic bile collected from the common duct, when the obstruction has persisted for one week or more, and the gallbladder contained calculi.

TABLE 7.—Hepatic Bile After Common Duct Obstruction

Patient	Calcium, Mg. per 100 Cc.	Chloride, Mg. per 100 Cc.	Bile Salt, Mg. per 100 Cc.	Cause of Obstruc- tion	Days Ob- structed
Br.....	6.8	280.0	0	Stone	20
Sh.....	10.8	472.0	116.5	Stone	4
He.....	7.8	353.5	0	Stone and cholangitis	21
St.....	5.0	347.6	0	Stricture	18
Je.....	8.0	355.6	0	Stone	6
An.....	6.8	358.3	0	Stricture	5
Ta.....	4.6	263.9	0	Stone	12
Do.....	4.0	463.1	0	Stone	40

An intimate experience with a number of such cases has led us to the conclusion that the interval between release of the obstruction and the reappearance of bile salt in the liver bile is directly related to the degree and duration of the obstruction and to the degree of cholangitis associated with the obstruction. The time of the reappearance of the bile salt may, we believe, be used as an indication of a return to normal liver activity.

The hepatic bile obtained after the release of an obstruction of the common bile duct has for a variable period of time a base concentration below that of the serum. The calcium fraction is in nearly every instance also low. The concentrations of both these substances tend to approach the blood level as the condition of the liver improves.

A very marked rise in hepatic bile chloride was often seen in patients who died after the release of an obstruction of the common bile duct. This finding has been so consistent that we have come to look on the return of the chloride concentration to the normal plasma level as indicative of improving functional activity of the liver and an increase in this concentration as of serious prognostic import.

The study of bile obtained from a number of sources after the institution of common duct drainage has convinced us that if the drainage was to remain until the bile was normal this objective was frequently not attained. In fact, drainage was often stopped before chemical evidences of any considerable degree of return to normal hepatic function were found.

It may be supposed that the loss of the total bile for short periods may rapidly result in a profound salt disturbance of the body. The calcium, sodium and chloride loss in the absence of cholerrhagia is not so great, however, but that these can be adequately taken

care of in the ordinary dietary, reinforced if necessary by the parenteral administration of sodium chloride. The fluid loss can also be adequately compensated for.

It is well known, however, that total bile diversion from the intestine for long periods is accompanied by serious consequences. More important than base and chloride is the loss of bile salts. From the standpoint of intestinal function the bile salts are of the greatest

Fig. 7.—Calcium precipitation in gallbladder wall.

Fig. 6.—Calcium precipitation in the gallbladder lumen.

importance. They aid in the activation of various lipases and in the emulsification and the transport of fat so that their loss from the intestine, even for short periods, seriously interferes with the known important extrahepatic functions of the bile.

We have no doubt that certain of the asthenias which are observed after the release of ductal obstructions and common duct drainage are associated with an interference of the processes of digestion and absorption. With this view in mind we have for several years made it a routine practice daily to place from 150 to 300 cc. of the drained bile into the duodenum through a Jutte tube. This method deserves a more widespread use in the postoperative therapy of common duct operations when bile diversion is taking place. Whether any other important substances are present in the bile that improve the condition of the patient cannot at this time be answered.

A better knowledge of the changes that are associated with disease of the biliary tract either in part or as a whole may, we hope, lead to better methods of preoperative and postoperative treatment and perhaps even to changes in the operative attack.

CONCLUSIONS

We have presented data showing certain changes that occur in the chemistry of the bile in various surgical lesions of the biliary tract.

These data demonstrate the direction of the changes from the normal chemistry of the bile which take place when either the liver or the gallbladder is damaged.

With increasing evidence of disease of the gallbladder wall there is in general a greater change in the chemical constitution of gallbladder bile from the normal.

Evidence is presented in relation to the bile salt-cholesterol ratio which, we believe, demonstrates that while a change in this ratio may be a factor in gallstone formation it is not the sole etiologic factor.

The changes that normally take place in hepatic bile once it enters the gallbladder are considerable. We subscribe to the concept that in man the gallbladder plays an important rôle in physiologic economy and should not be removed without definite evidence that its function is impaired.

When the liver becomes damaged either by infection or by obstruction of the extrahepatic bile ducts, profound changes occur in the chemical composition of hepatic bile.

Surgical drainage of the common duct is very often not continued until the composition of the hepatic bile returns to anywhere near normal values.

Of major importance when the hepatic bile is being drained exteriorly is the consideration of the extrahepatic functions of the bile. We believe that the daily feeding of bile to such patients aids materially in the rapidity with which convalescence may take place and in the prevention of asthenia in the patient whose hepatic bile is being drained over long periods.

3400 Spruce Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. GRAHAM AND MACKEY, IVY AND BERGH, AND RAVDIN, RIGEL, JOHNSTON AND MORRISON

DR. DONALD GUTHRIE, Sayre, Pa.: The present state of knowledge of liver function and of liver duct and gallbladder disease is due largely to the brilliant work of the physiologist, the biochemist and the experimental surgeon. This rapid advance in knowledge of these problems has armed the internist and the surgeon with safer methods of preoperative and post-operative treatment and has been responsible for better surgical procedures. In my clinic I have followed the suggestion of Dr. Ravdin and his associates of returning the bile loss in the presence of obstruction into the patient's gastro-intestinal tract and have found it a wise and helpful procedure: I also believe that the reappearance time and the concentration of the bile salts are valuable tests for the return of liver function. I agree with Drs. Graham and Mackey as to conservatism in management of the stoneless gallbladder, for the worst results have been in these unfortunate patients who remain in poor health or who have been made worse by the operation. One must be sure that the gallbladder disturbance is giving the patient the major part of his symptoms. These patients must give a history of one or more typical attacks before I will accept them for operation. Many of them may be helped by the medical measures suggested by Drs. Ivy and Bergh. I accept their idea of the choledochoduodenal system and I believe that disturbances in this system will explain not only many of the preoperative symptoms but also many of the unsatisfactory results that one sees after operation. In the presence of chronic gallbladder disease, duct disease, hepatitis, duct infections, duct obstructions and pancreatitis of various degrees, permanent damage has already been done to one or more of the important functions of the liver before the patient comes for relief by surgery. Gallbladders or stones may be removed and obstructions of the ducts may be relieved, but the damage that has already taken place in this complicated hepatic system cannot be repaired. Are not many of these unsatisfactory results following operation due to this fact, as well as to dysfunctions in the choledochoduodenal system?

DR. URBAN MAES, New Orleans: At the New Orleans session of the American Medical Association, Dr. Ravdin made

a statement in discussing a group of gallbladder papers to the effect that, after operations for biliary obstruction, bile salts are always absent from the bile for a time. Dr. Frederick F. Boyce of my staff in a series of experiments corroborated Dr. Ravdin's statements and added some observations. In studying obstruction of the biliary system by stone as compared with obstruction by carcinoma of the head of the pancreas or within the ampulla, Dr. Boyce found that in all the cases of malignancy observed the bile salts reappeared within a shorter period of time and their concentration progressed more rapidly than when the obstruction was due to stone. In all the cases of malignancy the duration of the obstruction was longer than in obstruction by stone and therefore we surmise that the infection of the intrahepatic biliary system which is an almost constant accompaniment of obstruction by stone is the factor responsible for both the delayed reappearance of the bile salts and for their slower concentration, although we realize, of course, that increase of pressure within the biliary system also plays a part. We have observed two special groups of patients. In one, typical gallbladder symptoms were associated with a marked enlargement of the liver, while in the other the x-rays without the use of dye showed a gallbladder characterized by thickening and stagnation. In both instances amebiasis could be demonstrated, and in both specific treatment for it resulted in complete relief of symptoms. The infectious processes undoubtedly are very important in the pathology of the stoneless gallbladder and I am convinced that the presence of an unsuspected and therefore undetected intrahepatic amebiasis may be responsible for some failures in the treatment of gallbladder disease.

DR. GEORGE A. HENDON, Louisville, Ky.: There has been a dispute concerning the advisability and feasibility of cholecystectomy. I have perhaps hit upon a plan by which this may be compromised. I have observed in clinical work that the gallbladder is more diseased at its fundus, and as one gets down toward the cystic duct one will find more durable gallbladder tissue. Therefore, on being confronted with conditions indicating that the gallbladder should be removed, I avoid the hazard of including or injuring the common duct as well as the hazard of hemorrhage from the cystic artery by leaving a small amount of gallbladder toward the cystic duct. I then pucker this together with a catgut ligature and leave one end of it long. I employ a tube about half an inch in diameter and cut it fishtail shaped at one end. By means of a long, straight needle, which is carried up inside the tube and brought out on one side, one can draw the puckered-up remains of gallbladder inside this tube, and while the long piece of ligature is being held taut by the assistant one can go down and sew both sides of the fishtail very snugly round the remnants of gallbladder. In this manner one preserves some gallbladder and avoids the hazards of injuring the common duct and provides for drainage. It matters not how well the cystic stump is ligated, there is always a little leakage of bile, at least in my experience, but if that occurs in this case it comes out through the tube that envelops the gallbladder stump. In the hepatic system that has become infected, drainage is the chief reliance and I do not mean drainage in the accustomed sense; I mean it in a broader and more philosophic sense.

DR. I. S. RAVDIN, Philadelphia: I think that Dr. Maes is right when he states that the rapid disappearance of bile salts in patients having obstruction of the bile ducts is probably largely associated with the cholangitis rather than the simple obstruction itself. The most rapid period of time in which the bile salts disappear in the dog are in those instances in which cholangitis is present together with obstruction. My associates and I did not present in this study patients who probably were suffering from dyskinetic lesions of the biliary tract. Lesions that affect the motor function of both the gallbladder and the extrahepatic bile ducts may also result in definite alterations in the chemistry of gallbladder bile. These are, however, not surgical lesions and the removal of such a gallbladder undoubtedly accounts for the relatively low proportion of good results that are obtained in noncalculous gallbladders. In regard to Dr. Hendon's statement of his method for attacking the gallbladder, if one permits even the smallest amount of gallbladder tissue to remain above the level of the highest heisterian valve some degree of gallbladder function

will continue and one cannot be sure that calculi will not reform. I believe, therefore, that it is essential that the surgeon go just as far down as possible. The technic that Dr. Hendon described may be used in a difficult case, but it should not be used as a routine practice in cholecystectomy.

DR. EVARTS A. GRAHAM, St. Louis: With reference to the point mentioned by Dr. Maes about obstruction of the common duct by malignant disease and by stone respectively, about ten years ago I observed that patients who have an obstruction of the common duct by malignant disease show a small amount of retention of phenoltetraiodophthalein in the blood stream, as compared with those who have an obstruction by stone. This is probably not a specific property of phenoltetraiodophthalein but would probably hold for any of the dyes that are used for so-called tests of liver function. I attribute this difference to the fact that in the cases of obstruction by stone one is dealing with an infection of the liver and in obstruction by malignant disease the amount of infection in the liver is insignificant. For ten years I have used this procedure with great help in the differentiation between obstruction by malignant disease on the one hand and by a stone on the other. The method used is described in my book on diseases of the gallbladder, published in 1928. I feel that it is practically always possible by means of a simple dye reaction, estimating the amount of dye retention in the blood stream after a certain period of time, to determine whether or not an obstruction is due to malignant disease or to a stone, except in those rare instances in which both conditions are present. It occasionally happens, of course, that one has a stone in the common duct in addition to a carcinoma, perhaps at the biliary ampulla, and in such cases one will get the reaction like that of stone rather than like that of malignant disease, because the infection associated with the stone overshadows the simple picture of obstruction by malignant disease.

DR. A. C. IVY, Chicago: I have nothing more to add, but I was pleased to find Drs. Graham and Mackey as conservative as I believe I am in regard to cholecystectomy.

FOOT IMBALANCE

REX L. DIVELEY, M.D.
KANSAS CITY, MO.

The problem of foot imbalance is one concerning which so much has been written that it would seem impossible to add anything new to the available literature dealing with its solution. Yet in spite of this voluminous literature the fact remains that the incidence of foot disorders due to foot imbalance is steadily mounting; moreover, the management of these disorders seems to be falling more and more into the hands of quacks, shoe salesmen and the manufacturers of various forms of arch supports. It appears then that the medical profession is failing in some way to meet the situation and that there is need of taking a more practical attitude toward this problem than has been held in the past. Admittedly, the treatment of foot conditions is troublesome, is uninspiring, and may even by some seem to be beneath the dignity of the profession, savoring too much of the chiropodist; yet foot imbalance is a health condition that is vitally affecting the efficiency and well being of a very considerable number of people and is well worthy of the thoughtful consideration and study of any physician. It is my object to present some practical facts that have proved helpful in the treatment of foot imbalance in the clinic.

In the space allotted it is impossible to consider even briefly the anatomic and physiologic aspects of foot

imbalance, nor will it permit of discussion of the etiology; for information on these subjects the reader is referred to the literature. This discussion will limit itself entirely to the diagnosis and treatment of the commoner forms of foot disorders.

From the clinical point of view it may be stated that there are two basic forms of foot imbalance: (1) the so-called flat or pronated foot with a low longitudinal

Fig. 1.—Type 1, the so-called flat or pronated foot, with a low longitudinal arch.

arch and (2) the high arched, adducted foot with a contracted plantar fascia and prominent ball. The combinations and variations of these two basic types are almost infinite in variety, but for practical purposes these two forms may be considered as presenting all the problems requiring solution in the treatment of simple foot imbalance.

Fig. 2.—Type 2, the high arched foot, with a contracted plantar fascia and prominent ball

DIAGNOSIS

The flat or pronated foot has as its principal characteristic the attitude of pronation to a varying degree and a depression of the longitudinal arch. As the body of the foot is adducted the forepart tends to adduct, resulting in a prominence of the scaphoid and internal cuneiform bones. The heel tendon and peroneal muscles are generally short or contracted, the former being

displaced laterally; this abnormal pull tends to increase the inversion of the foot.

In this type of foot a tired feeling and pain in the calf of the leg is the first symptom complained of. Later the pain is localized in the midtarsal region and through the instep; in extreme cases pain is distributed over the entire foot and various deformities evidence themselves.

The high arched type of foot is characterized by a high longitudinal arch with little or no pronation and a prominence of the ball of the foot. The heel tendon is generally short and spastic, the plantar fascia is tight and contracted, and the greater portion of the body weight is borne on the ball of the foot. With this type of foot is generally associated a fallen or depressed metatarsal arch with callosities, Morton's toe and hammer toe.

Pain in the high arched foot is usually localized in the ball of the foot; cramping at the base of the toes and pain in the calves of the legs are frequently complained of and at times pain through the instep or ankle may be added.

Fig. 3.—Fallen anterior arch with marked callosity formation, generally associated with the high arched type of foot.

TREATMENT

The aim of treatment in foot imbalance is to correct the faults present and thus make the foot as a whole work in an approximately normal manner so that each part functions properly. Thus one replaces the inharmonious and faulty action which must result when the foot is out of balance with some parts doing more than their share of work and others less than theirs.

Before the imbalanced foot can be brought into its correct posture, an accurate estimation

of its faults must be made by a careful examination. To facilitate this examination I have found a special foot examining stand, which places the feet on a level with the examiner's eyes as he is seated in front of the patient, most efficient and helpful.

This examining stand or platform is some 3 feet square and 20 inches high; on it is mounted a chair. Threaded from beneath the stand is a roll of ordinary white wrapping paper, which runs through a slot in the back of the platform beneath the chair and forward to the front of the stand. The loose end is held in a slot made on the front edge of the stand by a thin steel bar, which holds the paper in place and acts as a sharp edge on which to tear and remove the used pieces of paper. This allows a clean portion of paper for each patient on which diagrams and pedigraphs can be made.

A roll of adhesive plaster is held on a rack on the front face of the stand and a drawer just beneath this rack contains small instruments and measuring devices. A combination step and seat allows the patient to mount the examining stand and also serves the examiner as

Fig. 4.—Foot examining stand.

a seat. With the patient standing or seated on the examining platform, the foot may readily be inspected in various positions and departures from the normal noted. Some systematic method of examination should

Fig. 5.—Proper woman's oxford used for correction.

be followed and the observations recorded with exactness for future reference and comparison.

After the type and needs of the particular foot under examination have been decided on, the first step toward

correction is the ordering of a proper shoe, since this is the foundation on which correct balancing measures must be built. There are many different theories as to the proper type of shoe for the human foot; I do not propose to go into a discussion of the various types

Fig. 6—Stock sponge rubber inlay.

of footwear but wish merely to state that I have found that a shoe embodying the following characteristics gives the most uniform and satisfactory results:

1. The shoe should be of a bal or blucher oxford type.

Fig. 7—Shape, contour and placement of "flat foot type" of sponge rubber inlay.

2. It should have straight lines along the inner side and should curve not too abruptly backward on the outer side of the toe.

3. There should be ample room in the cap and ball of the shoe for normal function of the metatarsal arch and the toes.

Fig. 8.—Shape, contour and placement of "high arched type" of sponge rubber inlay.

4. The sole should be of the flat type and sufficiently heavy to give protection and support.

5. The heel should be of the straight side type, preferably extending slightly forward on the inner side of the shoe; height for men $\frac{6}{8}$ and for women from $\frac{12}{8}$ to $\frac{14}{8}$.

6. The counter should be narrow enough to fit the heel snugly and the vamp should lace rather firmly over the instep.

7. The shank should be rather broad and carry a steel built-in support from the heel to the bend of the sole at the metatarsal area to provide rigidity.

Such a shoe should be worn during the working hours of the day but may be replaced by a more pleasing and lighter shoe for dress occasions and evening wear.

The proper shoe having been fitted, the next step is the insertion into the shoe of the correct type of support needed to overcome the faults of balance present. It must be borne in mind that the most important element in this part of the treatment is that each foot is a problem in itself and that, while the basic principles of support are the same in all cases, the support must be varied to fit the needs of each particular foot under treatment. The type of support that I have found most satisfactory is made of sponge rubber of a fairly firm consistency. These supports are molded in various sizes and are composed of two principal parts, the longitudinal arch support and the anterior arch support.

The longitudinal portion of the arch is some three-eighths inch thick on the inner side and is beveled to a feather edge on the outside and to the rear, the bevel running forward to meet the anterior arch portion. This component part of the support fits under the longitudinal arch of the foot, tending to hold the bones of this arch in place, take the strain off the plantar fascia, and by its thrust on the inner side of the os calcis roll the foot outward and overcome pronation.

The anterior section of the inlay is rounded in shape and some three-sixteenths inch to one-fourth inch in height and is beveled abruptly forward; backward it tapers to meet the longitudinal portion, allowing a depression in which the first metatarsal rests as it crosses the support. This part of the inlay fits up under the anterior arch just behind the heads of the second, third and fourth metatarsals, the heads of the first and fifth falling on the medial and lateral sides of the support. The inlay in this position tends to elevate the metatarsal arch into the normal posture.

A rubber inlay of this type may be fashioned readily and skived to give the support necessary for correction as determined for each patient. For the altering and shaping of the inlay, scissors or a shoe cobbler's knife may be used to trim the support to the correct size and shape. The inlay is then skived and smoothed into its proper contour over a small, coarse, motor-driven emery wheel.

In the flat or pronated type of foot the principal correction should aim at overcoming the pronation by tilt-

Fig. 9—Imprint of inlay on ball of foot, acting as guide for adjustment.

ing the foot outward and supporting the longitudinal arch. The highest elevation of the medial side of the inlay should be beneath the neck and head of the astragalus, but the elevation should extend well toward the heel before sloping down, so that a definite thrust against the sustentaculum tali is secured. This is most important if a true outward rotation of the foot is to result. The anterior part of the support properly shaped takes care of any depression of the metatarsal arch present.

If a bunion or hallus valgus is present, the inner side of the transverse arch portion should be beveled off under the great toe joint and skived low just behind this area—that part on which the first metatarsal rests—to avoid pressure on the bunion.

In extreme cases of flat foot in which the arches are markedly depressed it is advisable to begin with a rather low inlay and gradually raise the longitudinal arch

Fig 10—Method of raising long or anterior arch of inlay by the addition of thin wedges of felt or sponge rubber.

portion as the foot becomes accustomed to the new position and the pressure of the support.

In the high arched type of foot the inlay should be of moderate thickness under the central portion of the longitudinal arch but be well skived out under the heel or cut off level with the anterior margin of the os calcis. In this type of foot there is little or no pronation, and therefore the foot must not be tilted outward but the high longitudinal portion of the inlay used only to take

Fig 11—Position and shape of metatarsal wedge to prevent the foot from rolling to the outer side of the shoe

strain off of the plantar fascia and the longitudinal arch of the foot. The anterior portion of the support should be fairly high and carried as far forward as is possible with comfort, as in this type of foot the strain falls principally on the metatarsal arch.

The support, having been fashioned, is then fitted to the sole of the foot and, if found correct, is ready for insertion into the shoe. Measurements are now made with an ordinary carpenter's caliper; the distance from the back of the heel to the head of the second meta-

Fig. 12—Position and shape of metatarsal bar to relieve metatarsalgia and prevent the ball of the foot from rolling to the outer side of the shoe.

tarsal bone is noted, pressure being made on the ball of the foot to tense the plantar structures. This measurement gives the approximate position of the anterior margin of the inlay from the back part of the heel on the insole. The medial or heavy side of the inlay is inserted flush against the inner margin of the insole and against the upper or counter of the shoe. After the inlay has been secured on the insole by two or three small tacks, the support is covered with a thin piece of leather or leather substitute, or the original sock lining of the shoe may be used.

The patient is now allowed to walk in the shoes and give the supports a temporary trial. If they seem

Fig 13—Shape, contour and placement of anterior heel: 1, position on insole, 2, lateral view, 3, anterior view.

comfortable the shoes are worn for two or three days, when the patient returns for further adjustment of the inlays. At subsequent visits when the shoes are removed it will be found on examining the sole that the imprint of the inlay is visible under the ball of the foot; this impression of the anterior portion of the inlay will act as a guide for future adjustments. The imprint of the anterior portion of the inlay should be evident between the heads of the first and fifth metatarsal bones and just behind the second, third and fourth metatarsal heads. It may also be found that too much pressure is being exerted by the support, in either the anterior or the longitudinal portion, in which case the inlay is removed and skived down to give the proper support. If sufficient support is not being given in any particular area, which will be judged by a nonrelief of the pain complained of, the support can be elevated on the under side by the addition of small wedges of felt or sponge rubber, which are glued into place. When the support is comfortable to the patient and complete relief is secured, the exact shape and contour with the

various measurements are noted on the permanent record.

As the foot is tilted outward to overcome the pronated position, it may be found that the forepart of the foot is shifting to the outer side of the shoe and the

1. 2.

Fig. 14.—Type of strapping to support the long arch of the foot.

lateral aspect of the fifth metatarsophalangeal joint is becoming irritated. In such a case a metatarsal wedge or dutchman of one-eighth inch thickness should be inserted on the outer side of the sole of the shoe, just beneath the head of the fifth metatarsal. This elevation will overcome the outward sliding of the forepart of the foot and will in addition add to the efficiency of

Fig. 15.—Type of strapping to support anterior arch of foot: 1, position of foot and toes for strapping; 2 and 3, views of strapping; 4, soft felt anterior heel can be incorporated in strapping for support.

the support under the longitudinal arch, as pointed out by Steindler.

In extreme cases of flat foot it may be found necessary to wedge the heel on the inner side or to extend

the heel forward on the medial side, as advocated by Thomas.

When a pump or high heel type of shoe is substituted for dress wear, only the anterior portion (anterior heel) of the support should be used; this usually gives sufficient support for a time and makes it possible to wear such a shoe for short periods when the patient is not going to be on the feet continuously.

Strapping of the feet should be used only as a temporary measure to relieve pain in acute cases. In the flat foot type of imbalance, in which the pain is localized in the long arch or in the midtarsal region, the strapping should aim at supporting the long arch (fig. 14).

In acute cases of anterior metatarsalgia, a temporary strapping of the anterior arch will aid in giving relief (fig. 15).

FOOT EXERCISES

Supports, shoes, braces and strapping may hold the foot in the corrected position and relieve pain and discomfort, but such measures must be considered as only

Fig. 16.—Exercise 1.

passive agents. One must add to these measures others of an active character, which will build up and restore tone to the muscles and ligaments, which are the true and natural supports of both the longitudinal and transverse arches. This building up can be accomplished only by exercises carefully planned and conscientiously executed.

The following exercises are designed to strengthen the various muscle groups the function of which is to give support and elasticity to the feet. The exercises should be carried out twice daily, preferably morning and evening, and of course always in the bare feet:

EXERCISE 1.—Toe gripping exercise. This exercise develops the musculature that supports the metatarsal arch of the foot.

Position: Sitting, with several marbles or jackstones on the floor.

Action: Grasp the marble or jackstone with the toes and pick it up, placing it a foot or so from its original position. Now replace the marbles to their original position with the other foot.

EXERCISE 2.—Foot adduction exercise (walking). This exercise stretches the muscles on the lateral side of the foot and strengthens the muscles on the medial side of the foot, which tends to hold the arches in the proper position. This is an excellent exercise to overcome "weak foot."

Position: Standing, ready to take a step. The foot is rolled to the outer side and the toes are forcibly flexed.

Fig. 17.—Exercise 2, lateral and front views.

Action: Take from twenty-five to fifty steps with the foot in this position. This position holds both the longitudinal arch and the metatarsal arch in their proper posture.

EXERCISE 3.—Heel stretching exercise (standing). This exercise stretches the heel tendon and strengthens the muscle groups that hold the arches in balance.

Position: Standing, facing and 3 or 4 feet from the wall. Toes are turned in and forcibly flexed and the body weight is rolled to the outer side of the foot.

Action: Lean on the wall with the arms straight, back rigid and head erect. Slowly flex the arms, keeping the back straight and the knees and hips extended and the heels firmly on the floor, until the head touches the wall, or as near as is possible, rolling the feet to the outer side. Hold this position for a few seconds, then slowly straighten the arms assuming the original position. Repeat this movement from ten to twenty times.

If you are doing this exercise properly you will feel the pull in the muscles on the back of the calf and thigh of the leg.

CONCLUSIONS

Foot imbalance is a very widespread and incapacitating health condition that is being cared for in a very inadequate manner, generally speaking. An adequate study of the needs of each case and a careful, painstaking and rational therapy will in the majority of instances result in complete or satisfactory relief. Failure to size up the situation properly or careless, slipshod methods of treatment cannot but result in failure, to the detriment of the patient and the reputation of the medical attendant. The methods here described have proved on the whole satisfactory and are presented not as an answer to the problem of foot imbalance but as a contribution to its management.

1600 Professional Building.

ABSTRACT OF DISCUSSION

DR. CARL E. BADGLEY, Ann Arbor, Mich.: I am not in accordance with Dr. Diveley's description of the two types of feet—the high-arched foot and the low-arched foot. It seems to me that the greatest difficulty is in the high-arched foot. I would add two other types seen associated with the high, bony, longitudinal arch, with marked pronation. As I understood Dr. Diveley, in cases of high-arched foot pronation does not occur. I have in mind two types, one described by Dr. Kidner, with the accessory scaphoid, and the other by Dr. Hoch, of the extremely relaxed foot. In my experience these two types of feet of the high-arched type give the most trouble. I have tried to correct this foot and found the foot plate during the growing period of the child most satisfactory. I utilized the Hoch operation for the relaxed foot and the Kidner operation for the scaphoid.

DR. THEODORE A. WILLIS, Cleveland: There is a controversy between two schools of treatment of flatfoot. On one side are the advocates of metal arches and rigid shank shoes and, on the other side, of the flexible arch and soft pads. Having been brought up in the school of rigid support, I have discarded its use and have been converted to the other side. The important thing in the treatment of flatfoot is the instruction of the patient in the proper use of his feet. One can help with shoes, but until the patient learns how to bear his weight, he isn't going to have permanent relief. Students of anatomy are taught to consider the foot as the movable terminus of a fixed leg. The anatomy textbooks state that the flexor hallucis longus flexes the great toe and the plantar reflexes the foot on the leg. When the foot is fixed, however, this muscle doesn't do anything to the toes. It pulls on the bone and joint pulleys at the ankle around which its tendon turns. The foot must be studied as a weight-bearing, fixed base for the propulsion of the body as a whole. The three muscles whose tendons lie behind the inner malleolus, the long plantar muscles on the inner side, are most important in the prevention and correction of flatfoot. Each serves a different function. Each has its individual action. The tibialis posterior presses the inner malleolus forward and pulls the navicular upward and backward. The flexor digitorum longus turns through a strong ligamentous tunnel on the inner side of the talus. When the

Fig. 18.—Exercise 3: first position, starting exercise; second position, completing exercise; at right, second position from behind.

forefoot is fixed, this muscle lifts forward, upward and outward, raising the arch of the foot. The flexor hallucis longus tendon turns behind the posterior border of the talus, pressing it forward, and then runs under the sustentaculum tali of the calcaneus, exerting an upward pull on this lever arm. It not only lifts the front end of the os calcis upward and outward but pulls the heel of the os calcis inward. Dr. Diveley's insole

tips the os calcis into a like position, but the patient must learn to do it habitually. A great deal is heard about tiptoe rising exercises for flatfoot. Tiptoe rising does nothing but develop the gastrocnemius. Exercises must be directed toward development of those particular muscles which are weak in the individual under treatment. Adhesive plaster strapping and the use of flexible supports are often of temporary benefit.

DR. LEWIS CLARK WAGNER, New York: The so-called flatfoot is easily treated but there is no one definite support that can be used by all patients. Muscle reeducation is most necessary. I feel somewhat against the use of steel plates, except for children. In dealing with the high arched foot with contraction of the plantar fascia and a cavus deformity, the treatment should be combined with surgery in extreme cases in order to restore the grasping power of the toes. Structural changes and deviation from the normal in the foot are often dependent on muscular imbalance, which leads to deformity and contraction of the toes with subsequent faulty weight bearing. This type of foot is characterized by a fairly high arch with loss of normal elasticity with or without a slight equinus due to contraction of the calf muscle. The etiology may be an inherited peculiarity but most likely the remnant of some disturbance of the cerebrospinal nervous system. A mild attack of poliomyelitis or some infectious disease of childhood or congenital syphilis can be the factor in the production of such conditions. When the deformity becomes extreme, the weight is thrown on the first metatarsal head and the great toe soon loses the grasping power in walking. Painful callosities develop on the dorsum of all the toes, but most severely on the first toe. Corresponding areas are found under the head of the first metatarsal bone. Inflammation and infection are often present. The accepted methods of treatment may be conservative (stretchings, tenotomies and foot plates) or directed to the removal of the deforming influences by transplanting the extensor tendons of the foot into the metatarsal heads with arthrodesis of the interphalangeal joints. When the extensor hallucis longus is transplanted to the metatarsal head, the elevation in the metatarsal bone is secured and normal grasping power of the great toe is returned, but dorsiflexion is lost, which makes walking difficult in the bare feet because of the dropped toe. By transplanting the extensor tendon of the fifth toe to the base of the first phalangeal joint, this difficulty can be obviated and a very satisfactory foot secured. The sesamoid bone of the great toe should be removed in extreme cases, as it will often be found distorted or inflamed because of the persistent trauma in its region.

DR. J. J. KURLANDER, Cleveland: A reasonably large number of cases of foot imbalance are due to a mild infantile paralysis that is unrecognized. I treat a considerable number of feet. In applying a plaster cast to the foot and leg for a fracture or other conditions I make it a practice to mold the cast under the arch and under the metatarsal head and in this way restore the proper foot alignment, often curing or relieving a foot condition that I did not know existed at the time. A painful foot may be an early manifestation of peripheral vascular disease; for that reason no foot examination is complete without palpating for the pulsation of the dorsalis pedis artery. An absence of pulsation is often the first sign of thrombo-angiitis obliterans. Many people have a condition which I call "chauffeurs' foot," from pressing down on the brakes or accelerator of their automobiles in such a manner that the toes are forced upward and the metatarsal heads downward. A simple way to relieve this painful condition is to instruct these patients to catch the pedals behind the heads of the metatarsals. This will force the heads up and the toes down. I do not use metal arch supports. I think the rigid arch should be reserved for acute arthritis. If the arthritis is so severe that one needs a rigid support, in all probability that patient ought to be entirely off his feet, instead of walking about. Flatfoot is due to two causes (besides paralysis): (1) overuse of the muscles, with resultant fatigue and relaxation, or (2) weakness of the muscles from too little use. In mild cases of "hollow foot," the metatarsal arch should be elevated by the use of a felt pad. But in severe cases, operative procedures, such as tenotomies or fasciotomy, may be necessary.

DR. REX L. DIVELEY, Kansas City, Mo.: Many have mentioned the successful use of the Whitman plate or other rigid metal arch supports, which are inserted in the shoe. I concur in the fact that this type of support has given excellent results; but the Whitman plate was devised for use when a rigid shank shoe was not obtainable. In using a flexible shank shoe, it is necessary to use some type of an inserted steel support; however, the majority of the shoe manufacturers are now building their shoes with a rigid shank; in other words, the steel support is built into the wide shank of the shoe. I have found it more satisfactory to use the rigid shank shoe, into which I insert the sponge rubber support, which is more easily fashioned and shaped and is much more comfortable to the patient and, I feel, is just as efficient as the Whitman plate. I agree that exercises are most important. It is my practice, however, to relieve patients of their pain by properly balancing the foot with shoes and supports, and then when relief has been obtained to build up the feet with proper foot exercises. It is interesting to note the attitude of the average orthopedic surgeon toward simple foot imbalance. Last week while attending the meeting of the American Orthopedic Association I asked three representative surgeons how they treated foot imbalance. The first replied: "About the only feet I see are of women with acute metatarsalgia and I manipulate and massage these feet once and generally never see them again. They are cured." The second man said: "We don't have very much foot trouble in our part of the country, so I do not pay very much attention to that aspect of orthopedics." The third one replied: "We have very little difficulty with foot conditions, although we see quite a number. We have an excellent brace maker and I just turn the patient over to him. He knows what they need and I do not bother with them again." Considering these three typical replies, one may draw the conclusion that the treatment of simple foot imbalance is a forgotten or neglected art with most orthopedic surgeons.

ELECTROCOAGULATION OF CERVICAL EROSIONS AND ENDOCERVICITIS IN THE LATE PUERPERIUM

A STUDY OF FOLLOW-UP RESULTS IN A SERIES
OF PATIENTS DELIVERED AT THE
WOMAN'S HOSPITAL

RALPH L. BARRETT, M.D.
Junior Attending Surgeon, Woman's Hospital
NEW YORK

It is our practice in the obstetric service of the Woman's Hospital to inspect the cervix at the end of the third stage of labor. If lacerations of 1 cm. or more are found, they are immediately sutured unless there are contraindications such as shock or infection. Patients are observed in the follow-up clinic for a period of from eight to sixteen weeks following delivery. This follow up has shown an unsatisfactory condition of the cervix in about one half of these women.

Trauma of some degree exists in practically all cervixes after delivery, and it is well known that many cervixes are the seat of chronic inflammatory conditions which antedate the first pregnancy. A careful study of the cervix at the sixth week post partum shows a good involution and healing in about one half of the patients. If lacerations and erosions are unhealed at the end of the eighth week, the condition tends to become chronic with an increased growth of the glandular epithelium, secondary infection, cervicitis and endocervicitis. These conditions are frequently responsible for persistent leukorrhea, pelvic pain and sacral

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

backache along the course of the sacral lymphatics and nerves as well as for many cases of menstrual irregularity and menorrhagia due to faulty postpartal involution of the uterus.

It is the belief of many well known gynecologists that unhealed cervical lacerations, chronic cervicitis and

in which they had made a postpuerperal note to the effect that the cervix was healed.

E. Starr Judd⁵ and C. Jeff Miller,⁶ in articles dealing with this subject, concur in these opinions. Miller states that there is no doubt that endocervicitis is a condition to which that much abused word "precancerous" may be truly applied.

Culbertson⁷ and Eden have called attention to certain types of erosion showing extensive proliferation of cells, which clearly place the disease on the borderline of malignancy.

Matthews⁸ has pointed out that it is but a step from the extreme cell proliferation with orderly arrangement, which occurs in marked cystic hyperplastic endocervicitis, to the disorderly arrangement with embryonal cells found in true malignancy. Postpartal care would seem to be as important as antepartal observation. Cervical lesions should be corrected soon after delivery; if neglected, they may later need radical treatment.

H. A. Miller⁴ has shown that erosions of the cervix in varying degree are present in 80 per cent of multiparas and in 10 per cent of primiparas. Culture of the cervix in more than 10 per cent of these women yielded streptococci. To assist in preventing the sequelae of lacerations and erosions, and as a prophylactic against infection in subsequent pregnancies, he advocates the early correction of the diseased condition of the cervix.

Fig. 1 (case 1).—Laceration and extensive erosion of the cervix in a primipara, before treatment, eight weeks post partum. From life drawing.

endocervicitis, with their subsequent structural changes, furnish a favorable site for the future development of cancer.

Crossen¹ is of the opinion that it is a well established fact that cancer of the cervix comes from long continued irritation in the form of endocervicitis, usually accompanied by lacerations, erosions and cystic changes. Great pains are taken to detect the first signs of cancer so that treatment can be promptly instituted, whereas a far safer plan is to remove the chronic cervicitis early before it becomes a cancer. An important step in preventing cancer is early removal of the chronic lesions of the cervix which precede the cancer. This seems to be the only means by which a further marked reduction in the deaths from this disease can be secured. It is dangerous to allow irritation in the cervix to persist even during the child-bearing period.

Pemberton² cites 1,087 cases in which repair of the cervix was done. Cancer developed in from five to thirty-six years in only twenty-three of this group.

Norris³ mentions 1,247 patients treated for chronic cervical erosions in only one of whom cancer of the cervix was known to have developed.

H. A. Miller and his associates⁴ state that to their knowledge no case of cancer of the cervix has occurred

Fig. 2 (case 1).—Appearance immediately after electrocoagulation of the cervix, showing the white coagulum. From life drawing.

Goodall⁹ believes that a previously damaged and infected cervix that has not been cleared up is a fre-

quent source of pelvic thrombophlebitis in subsequent pregnancies.

Brown¹⁰ and Baker¹¹ stress the importance of chronic cervical infection as a starting point for puerperal sepsis and as a focus for systemic toxemia.

Fig 3 (case 1)—Four weeks after electrocoagulation. The coagulum has completely separated, with shrinkage of the cervix. Islands of epithelialization are noted. From life drawing.

At the Woman's Hospital it was decided to treat a series of patients with damaged cervixes during the late puerperium. The method chosen was electrocoagulation. By its use heat is generated within the tissues, penetrating deeply enough to destroy the diseased tissue and to cause instantaneous thrombosis and so prevent hemorrhage. Electrocoagulation produces a complete cellular necrosis. Ground¹² has proved that the sterilizing effect of the heat extends much farther than the visible coagulation; thus, there is a zone around the coagulated area that is lethal to micro-organisms, and yet the heat is not sufficient to destroy normal tissue cells. Electrocoagulation is unaffected by quenching in the mucus of the cervical canal and is not subject to the self limiting action of charring and carbonization that occurs with the actual cautery. This carbonization prevents uniform penetration and destruction of diseased tissue, and there is a far greater tendency to primary or secondary hemorrhage when the slough separates.

The cervix has been coagulated in a series of 120 patients who have been followed at least three months since the completion of treatment. We have treated all the cervixes by a uniform technic using an electro-

surgical diathermy machine operating on a frequency of about one million cycles a second with a corresponding wavelength of 300 meters. The voltage is low and variable; it is never more than 400 volts with any setting of this machine, the usual setting registering about 110 volts. The milliamperage used in coagulation is from 400 to 600 milliamperes.

The active electrode is an ordinary ball coagulating tip, the inactive electrode being a woven mesh strip placed about the patient's thigh. In the removal of polyps and for biopsy purposes a wire loop has replaced the ball electrode. This machine has an entirely separated patient's current, which is only inductively coupled to the oscillating current. It is therefore safe for the patient under all circumstances, because there is no direct connection between the patient's current and the electric mains.

Ende¹³ has shown that there must always be a variable factor, owing to the variation in resistance of the individual patient, caused by such factors as size and tissue density. Measurement of the individual tissue resistance is possible but not practicable, because of the technical apparatus and the time consumed.

All treatments were carried out under local anesthesia of 2 per cent nupercaine applied topically on cotton pledgets. This has given very satisfactory local anesthesia, although when the coagulation is carried out high in the canal there may be some complaint of uterine cramps. In the cases requiring coagulation high

Fig 4 (case 1)—Six weeks after electrocoagulation. The cervix has a normal appearance. From life drawing.

in the canal, it is advisable that a wide dilatation of the cervix should first be done.

The coagulation is easily and quickly accomplished by a sweeping motion over the entire diseased area producing a white or grayish coagulum, carbonization,

indicated by excessive sparking, being avoided at all times. Experience has taught that the best results are obtained by light rather than deep coagulation, the penetration being, as a rule, from 2 to 5 mm.

The first seven to fourteen days following coagulation there is a free leukorrhea, often blood tinged. This

Of the 120 patients in this series, ninety were from the clinic service and thirty from private practice. Eighty-one were primiparas and thirty-nine multiparas. A second coagulation was done in only two patients in the group. Three of the patients in the group had had primary repair of the cervix at the time of delivery. All these women showed lacerations, erosions and endocervicitis of varying degree. Only two patients in this series had postoperative bleeding requiring packing, one on the eighth day and one on the fourteenth day. Healing in these two patients was not delayed in any way.

Histologic sections from cervixes following electrocoagulation have been reported by Royston,¹⁴ Kimble¹⁵ and Hyams.¹⁶ These authors agree that healing takes place without scar formation and that the healed surface is covered by normal squamous stratified epithelium.

The accompanying tables summarize the extent of cervical damage together with the chief signs and symptoms exhibited by this group of 120 patients.

Fig. 5 (case 2).—Extensive stellate laceration, erosion and endocervicitis in a multipara eight weeks post partum. From life drawing.

All the 120 patients have completed at least three menstrual periods since the treatment. In no case is there evidence of cervical stenosis. Four patients of the private group have been delivered by the vaginal route without cervical dystocia. Four patients are now pregnant from two to six months. Two patients in the clinic group were treated by electrocoagulation while in the early weeks of an unrecognized pregnancy. The pregnancy was undisturbed. There are three women of the group of 120 who still complain of leukorrhea. Two of these patients suffer from *Trichomonas vaginalis* vaginitis and in the third patient the cause of the leukorrhea has not as yet been determined.

14. Royston, G. D., and Roblee, M. A.: *Am. J. Obst. & Gynec.* 24: 381 (Sept.) 1932.

15. Kimble, H. E.: *Arch. Phys. Therapy* 14: 550-553 (Sept.) 1933.

16. Hyams, M. N.: *Arch. Phys. Therapy* 11: 171-178 (April) 1930.

persists until the coagulum has separated, after which there is rapid healing, usually complete in from four to six weeks. By the fifth or sixth week it has been found that the cervix has shrunk to normal dimensions, lacerations are healed and all eroded surfaces are completely epithelialized.

All patients in this series were carefully selected to exclude any pelvic inflammatory disease. It is perhaps due to this careful selection that there was no lighting up of pelvic inflammatory reaction following coagulation.

In this group of 120 patients there are no unhealed cervixes and no gross pathologic conditions are evident.

SUMMARY

1. A careful study at the eighth week post partum showed unhealed cervical damage in at least 50 per cent of all women in our series.

2. Unhealed cervical lacerations and erosions favor the future development of chronic cervicitis, endocervicitis and hypertrophy.

3. Chronic cervicitis and endocervicitis with the subsequent structural changes make the cervix a favorable site for the future development of cancer.

4. A chronically infected cervix is a possible source of thrombophlebitis and general sepsis in subsequent pregnancies.

Fig. 6 (case 2).—Condition of cervix six weeks after electrocoagulation. From life drawing.

5. Cervical lacerations and erosions may be corrected safely and easily in the late puerperium by electrocoagulation.

6. Electrocoagulation, owing to its uniform penetration and destruction of diseased tissue without carbonization, is superior to cauterization in the treatment of cervical injuries in the late puerperium.

7. Healing, following electrocoagulation of the cervix, results in a smooth pliable epithelialized surface free from scar formation.

8. In a series of 120 patients, no stenosis of the cervix has occurred following electrocoagulation in the late puerperium.

9. All patients in this series were treated in the office or outpatient department. There are no unhealed cervixes and no gross pathologic changes are evident.

59 East Fifty-Fourth Street.

ABSTRACT OF DISCUSSION

DR. JOSEPH B. DE LEE, Chicago: Those who saw my motion picture of forceps and episiotomy on the screen yesterday will note that there was very little laceration visible to the eye. On the left side there was a tiny mucous split but, as I said, the mucosa was intact. Magnified on the screen it impressed one, but in actual life it wasn't more than an eighth of an inch in extent and possibly a sixteenth of an inch deep. But the mucosa being intact does not mean that the cervical wall muscle was intact. It wasn't. It was torn on both sides submucosally and the muscle tissue had separated and then was so thin that one could have squeezed it together to the thickness of ordinary paper. The head, in coming down after that cervix was dilated, pushed the mucosa of the endocervical region ahead of it and everted it, very much like the anus of a horse after defecation. Nature does not always pull that mucosa back into the cervix, and this is really not a laceration. It is an overdistention of the cervix. I think one ought to distinguish between actual overdistentions and destruction of the muscle submucosally, from an actual bilateral laceration. It is almost impossible to sew up such a submucous laceration. The treatment shown by Dr. Barrett is possibly the best method at present of restoring a condition of that kind to the natural.

DR. A. H. CURTIS, Chicago: I wish to bring out one point: Either correction of an important lesion of the cervix may be made with the method that has been presented, which is very efficacious, or the very extensively diseased cervix may be removed surgically. There has been a tendency, when one encounters a markedly diseased cervix suspected of harboring a cancer or in which one fears the development of a cancer, to remove a fragment or two for histologic study. In those cases in which one is morally certain that there is no malignant condition but in which a biopsy is made for the sake of safety, I believe the entire lesion should be removed. Then safety has been secured not only for that moment but for several years following; otherwise the patient will have to be kept under constant surveillance.

DR. RALPH L. BARRETT, New York: This was a carefully selected group of cases treated in the late puerperium. It was not intended to treat all cases of endocervicitis. This was a trial to see what could be done with electrocoagulation in the late puerperium. The cases were carefully selected, extensive cystic and hypertrophied cervixes were excluded. I attempted to cure those lesions which I thought had been produced by the recent pregnancy and labor. The pictures that the artist drew of these patients from life at the time of treatment and in subsequent weeks would seem to indicate that this simple procedure has corrected a large number of lesions. Very few of these cervical lesions were extensive. When biopsy was taken, an electrosurgical diathermy loop was used to obtain as much material as possible. No malignant changes were found.

DR. DE LEE: How deep do you think that slough was: how many millimeters?

DR. BARRETT: From 2 to 5 mm. as well as I could measure. I have no microscopic section made at the time.

Nature of Hodgkin's Disease.—The most important views as to the nature of Hodgkin's disease are that it is either: (1) an infection of unknown nature (lymphogranuloma) (German school, Longcope, MacCallum, Symmers, etc.); (2) an atypical form of tuberculosis (Sternberg, l'Esperance); (3) a lymphoblastoma (Mallory, Warthin); (4) a megakaryocytoma (Medlar); (5) a disease intermediate between infection and neoplasm (Lubarsch, Levin). The proper nosologic position of Hodgkin's disease is far from being, as some would have it, an almost wholly academic question. The direction of further study, with eventual practical matters of diagnostic and therapeutic importance, obviously are largely conditioned by one's attitude to such nosologic aspects. . . . While the nature of Hodgkin's disease remains obscure, the preponderance of evidence favors the infectious theory, with some promising support for its inclusion among the virus diseases.—Krumbhaar, E. B.: *Am. J. M. Sc.* 188:597 (Nov.) 1934.

ARGYREMIA

DETECTION OF UNSUSPECTED AND OBSCURE ARGYRIA
BY THE SPECTROGRAPHIC DEMONSTRATION
OF HIGH BLOOD SILVER

HAROLD BLUMBERG, Sc.D.

Assistant in Pediatrics, Johns Hopkins University School of Medicine
AND

T. NELSON CAREY, M.D.

Associate in Medicine, University of Maryland School of Medicine and
College of Physicians and Surgeons
BALTIMORE

Argyria, the discoloration of skin or tissues caused by silver absorption, is considered extremely rare in modern medicine, but during the past few years it has reappeared with surprising frequency. The history of the subject, known also as argyrosis or argyrism, has been adequately reviewed by Gettler, Rhoads and Weiss¹ and by David.² According to its nature, argyria is designated as local or general; according to its origin it is occupational (professional) or therapeutic. The awakened interest in the subject is due to an increased occurrence of generalized argyria of therapeutic origin.

Many new cases have been caused by the intranasal and intra-oral administration of organic and inorganic silver compounds in colloidal form.³ In these instances argyria has resulted not so much from treatment by the medical profession but from the lay practice of administering the preparations, particularly to children, as a daily routine for the prevention of colds. Other cases have developed during the silver arsphenamine treatment of syphilis.⁴ Recently, Gernez⁵ and others⁶ have described a veritable epidemic of generalized argyria in northern France, caused by the prolonged administration of capsules containing collargol (a colloidal silver preparation) in treating pulmonary tuberculosis. From these considerations it is apparent that the untoward results of silver medication deserve attention; indeed, the comments of Knack⁷ on the danger of internal silver therapy were echoed in THE JOURNAL not long ago.⁸

Thus far we have mentioned only comparatively new silver preparations and uses. In this summary must be

included those cases produced, as were the classic cases of argyria, by the oral administration of silver nitrate in tabes, epilepsy and gastritis. Although this treatment has almost been abandoned, there are still occasional reports of argyria resulting from the use of silver nitrate in gastro-intestinal disorders.⁷ These cases are a striking reminder that the practice lingers on, and it is with another instance of this kind that the present report deals, in which an unsuspected and obscure argyria is described that was detected by the demonstration of marked argyremia, or high blood silver, during a spectrographic examination of the blood.

REPORT OF CASE

A white woman, aged 33, admitted to the University Hospital, Oct. 30, 1933, complained of frontal and temporal headache, pain in the back, gastro-intestinal discomfort, weakness, and loss of weight.

The patient had a history of ill health since 1918. Her symptoms during this period were similar to those complained of by her mother, who had been "nervous" most of her life and who had been nursed by the patient for ten years. There was doubtful typhoid in the autumn of 1930.

In January 1932 the patient's gastro-intestinal symptoms became so severe that she was operated on, but no pathologic abdominal condition was found except a displaced right kidney, which was put into position at a later operation. In October 1932 most of the teeth were removed, after which she was in a semicomatose state for several months, with no evidence of postoperative sepsis. She recovered partially from this early in 1933 and from that time until admission remained in bed, complaining chiefly of pain on swallowing, constant abdominal pain, and headache. During this period her room was kept darkened. Loss of weight continued to a marked extent; the intake of food was very limited.

On admission the patient was extremely emaciated, with loss of practically all subcutaneous fat; she weighed only 72 pounds (32.7 Kg.). The skin was bound down tightly to the underlying structures, especially over the forearms, hands and feet. The skin was scaly; the hair was normal in quantity and distribution. A very peculiar ashen pallor was noted. The mucous membranes of the mouth were extremely pale and the teeth were absent, with the exception of the lower cuspids and incisors. The gingival portions of these teeth were coated with a dark calculus and were surrounded by moderate pyorrhea. In the gum margin about these teeth there was a very definite gray-blue pigmentation with a punctate distribution; this was in the gum itself and not due to the deposit on the teeth.

The extremities showed stiffening of most of the joints, especially in the wrists, fingers and ankles. The ankles were fixed in full extension. The neurologic examination was negative, and the extension of the feet was not thought to be due to muscular paralysis. The remainder of the examination was negative, except for the abdominal scars, emaciation and a marked apathy.

Laboratory reports were as follows: Urinalyses were consistently negative; blood and spinal fluid Wassermann tests were negative; gastric analysis showed the presence of hydrochloric acid. The average of several blood pictures showed hemoglobin 4.2 Gm., red blood cells 1,990,000, white blood cells 2,700, color index 0.9. The differential count was polymorphonuclears 22 per cent, polymorphonuclear eosinophils 4 per cent, small lymphocytes 52 per cent, and monocytes 22 per cent. No abnormal white cells were seen; there was a slight diffuse basophilia but no stippling. The picture suggested a secondary anemia, possibly aplastic.

Although no history of exposure to lead could be obtained and the blood picture was not characteristic, the possibility of lead poisoning was suggested by the gum line, by the anemia and, to a lesser degree, by the foot drop. Accordingly, a sample of blood was taken for spectrographic examination for lead. The results indicated only a faint, nonpathologic trace of lead, but during the examination comparatively heavy silver lines were observed.

Aided by a grant from the Hartley Corporation.

As a result of this, inquiry was made with respect to silver absorption and the possibility of argyria. It was found that for the entire preceding year the patient had been taking capsules containing silver nitrate for gastro-intestinal symptoms. Each capsule contained one-fourth grain (16 mg.) of silver nitrate, and they were taken three times a day for alternate periods of two weeks.

To the clinical impression of psychoneurosis and nutritional anemia, which were indicated by other studies, were added the diagnoses of early argyria as the cause of the gum line and peculiar pallor, and silver intoxication as a partial cause of the anemia and asthenia. As a complete summary of the clinical study of the patient is not important for this report, it is not included.

The diagnosis of argyria thus made was verified by further studies of the blood and several other body constituents.

SPECTROGRAPHIC ANALYSES

The spectrographic analyses of the blood, as well as of the other materials, were made with a Hilger E 1 large quartz spectrograph, in combination with a graphite arc. Except when

The dots mark the positions of the silver lines, the left one at 3,280.67 and the right one at 3,382.89 angstrom units. The heavy line between the two is in reality a pair of lines, caused by sodium. 1. In the first spectrogram, a is the control spectrum of the empty graphite electrodes; b is the spectrum of the blood ash from the case of argyria, taken two weeks after the end of silver absorption, and c is again the graphite. Notice that the silver reference lines are not photographed in c, because argyria was not suspected at the time. 2. a, graphite; b, normal blood ash, but with known silver salt for reference lines in c; note that the silver lines are practically absent in b. 3. a, graphite; b, argyria blood ash three months after end of absorption; note persistence of marked argyria, as indicated by silver lines in b; c, silver. 4. a, graphite; b, normal urine ash; c, argyria urine ash; note presence of silver lines in c, showing elimination of silver three months after end of absorption. 5. a, graphite; b, silver nitrate capsule, illustrating the high content of silver; c, silver.

specified otherwise, the technic followed was similar to that used in the blood lead method described by Shipley, Scott and Blumberg.⁹ This analysis requires the ash from 5 cc. of blood and may be completed within from twelve to twenty-four hours. The silver lines demonstrated were the two characteristic "raies ultimes," or most persistent lines, with wavelengths of 3,280.67 and 3,382.89 angstrom units.

Blood.—It is interesting that marked argyria, or high blood silver, apparently has never before been reported in

argyria. Particularly striking is the fact that Gernez and his co-workers,¹⁰ using a chemical method, did not even detect silver in the blood, either during or after collargol ingestion. In our case, on the other hand, it was by means of the high blood silver that the obscure argyria was recognized. Generalized argyria implies vascular transportation, and it is extremely unlikely that the metal is carried exclusively, if even appreciably, by the lymph. Consequently, silver must at some time be present in the blood, probably as the albuminate, chloride and silver ion, regardless of the form in which it is ingested.

In the spectrograms shown here it is seen that the silver lines are comparatively heavy in the blood of our patient, whereas they appear as very faint traces, or are absent, in normal controls. The spectrographic detection of traces of silver in normal blood has been reported.¹⁰ By inspecting a series of more than 200 blood analyses, we found that faint traces of silver frequently occurred, especially in children. However, in some samples it could not be detected, so we cannot consider silver a normal constituent of blood on the basis of our analyses.

By means of standard spectrograms made by adding a known amount of silver nitrate to a silver-free blood, a quantitative estimation of blood silver was made possible. In terms of absolute sensitivity, as little as 0.000005 mg. (0.005 microgram) could be detected. With the ash method, the silver lines would appear at a concentration of 0.0005 mg. per hundred cubic centimeters. By comparison with the intensity of the silver lines in the standard spectrograms, the blood silver in the case of argyria was estimated to be 0.05 mg. per hundred cubic centimeters in the earliest sample, which had been taken two weeks after absorption had ended. This value is almost as high as the figures found for blood lead in lead poisoning.¹¹ During the actual time of absorption, the blood silver concentration must have been closer to 0.1 mg. per hundred cubic centimeters.

When a rapid liquid method was employed on an oxalated sample, silver could be detected in a single drop of the patient's blood. A micromethod in which 0.1 cc. of finger-tip blood was delivered directly onto a cored graphite electrode revealed silver quite definitely; in control samples, of course, the metal could not be detected. This may be used as a thirty minute method for detecting high blood silver in peripheral blood.

The distribution of the blood silver was determined from heparinized, oxalated and clotted samples. In our case of marked argyria, as well as in the frequent normal traces, the major part of the silver resided in the plasma or serum. Since the heparinized cells still contained silver after two saline washings, it is probable that a minor part of the silver was truly adherent to the cell fraction.

In normal children we have found that the trace of silver does not appear consistently, and in some cases the occurrence has been roughly correlated with periods of administration of mild silver protein. Our patient, however, exhibited not only a marked but a persistent argyria. The high blood silver was first detected two weeks after the silver ingestion had ceased. At the time of the last analysis, made three months after the end of exposure, the blood silver showed only a small decrease. This persistence of silver in the blood was not entirely unexpected, because it has been found that the blood lead remains high for many months following lead intoxication.¹¹ However, the duration and extent of the argyria proved that the silver was consistently circulating and had not been detected during temporary transit. It appeared, therefore, that the patient's tissues contained a heavy deposit of the metal, part of which was still in a soluble form.

In order to learn more of the persistence of silver in the blood, samples were secured from three old cases of argyria in which the pigmentation had been present for more than ten years. The analyses showed only faint traces of the metal. This demonstrated the eventual departure of abnormal silver from the blood.

Urine.—Charcot¹² mentioned the excretion of silver through the kidney, but the observation had never been confirmed by modern analyses. Although Gernez and his co-workers^{6c} detected silver in the bile, they were unable to find it in the urine, using chemical and spectrographic methods. In our case a high urinary silver was easily demonstrated, as shown in the accompanying illustration, even three months after the last ingestion of silver. In normal urines, as well as in the urine in an old case of argyria, the metal was detected in only faint traces or not at all. These results revealed a partial silver elimination, similar to the deleading following lead intoxication.

Feces.—The feces also showed high silver, although only faint traces were present in controls and in a sample from an old case of argyria. This demonstrated that the gastrointestinal tract also aided in silver elimination.

Cerebrospinal Fluid.—A moderate trace of silver was detected in the cerebrospinal fluid, whereas in controls it appeared in only very faint traces or not at all.

Saliva.—Saliva was secured after pilocarpine stimulation; obtained in this way, the sample was less likely to be contaminated by food debris. The result showed a definite trace of silver, while the metal was present as a very faint trace or was absent in controls. Although the conditions of sampling prevent a positive statement, it appears probable that silver was contained in the salivary secretion.

Skin.—Spectrographic demonstrations of silver have been reported in excised pieces of pigmented skin in argyria,¹³ as well as in the hair and nails.^{6c} As a result of a biopsy that had been made for suspected scleroderma, we had available a very small piece of undarkened abdominal skin. After a thorough rinsing in distilled water, the skin was dried and analyzed directly without ashing. Since there had been no contamination with silver in the pathology department, the detection of heavy traces of silver proved that there was a potential argyria in the absence of the dark pigmented forms of silver, which are probably the oxide, sulphide and metallic silver, in addition to some unknown form. Control skin analyses showed only a very faint trace of the metal.

Dental Tartar.—Lacking ethical justification for biopsy, we were unable to complete our story by identifying the pigment that started the investigation—the gingival “lead” line. However, the discoloration was also present on the lower teeth; so the deposits of dark tartar were removed for analysis. This material revealed heavy traces of silver, while a control sample showed only a doubtful trace.

AMOUNT OF SILVER INGESTED

It has been estimated that signs of argyria may appear after the absorption of only 2 Gm. of silver nitrate.¹⁴ In our case, the capsule used was supposed to contain one-fourth grain of silver nitrate, and the dosage was one capsule, taken three times a day. By alternate administration for from two to three weeks, and withdrawal for two weeks, the treatment had been maintained for a year. The total ingestion, then, was approximately 10 Gm. of silver nitrate, which is equivalent to about 6.4 Gm. of silver. In comparison with the literature this figure is not high, yet it is much above the lowest amounts that may produce argyria.

COMMENT

An interesting feature of the case is that, despite the peculiar pallor, there was no obvious brown, blue, gray or black pigmentation other than the gingival lines and the nonspecific dental discoloration. The blue-gray “silver” gum line is considered an early sign of argyria, although it is absent in many cases. It might be that the generalized pigmentation would develop more clearly in the future, for Gernez³ has commented on the retarded appearance of the discoloration.

Nevertheless, it is perhaps significant that the patient was not exposed to strong light during the period of silver treatment. Since the discoloration occurs chiefly in the exposed parts of the body, that is, the face and hands, it must be assumed that light may play a rôle in the pigment production. Furthermore, Zacks¹⁵ has reported the sudden appearance of argyria after ultraviolet irradiation of a child who had received mild silver protein intranasally for a long time. We were unable to attempt prolonged irradiation of our patient for fear that the experiment would be successful. By reason of its fixative action on the silver in unpigmented skin, light would appear detrimental to the partial elimination of silver from the body. Consequently, patients who are developing argyria, or who are in danger of doing so, probably should avoid strong illumination for many months after silver absorption has ceased.

Except for the extremely undesirable pigmentation, no harmful effects of chronic silver absorption have been definitely established. Although anemia and asthenia, as well as digestive disturbances,⁵ have been noted with suspicious frequency, there is as yet insufficient evidence to consider argyria a sign of true intoxication. In view of the hemolytic action of silver, however, it is probable that the effect of the metal contributed to the anemia and asthenia in our case.

The detection of this obscure case of argyria has provided an example of the value of spectrographic analysis in diagnosing suspected intoxications. In this case of argyria the gingival line was present; the demonstration of marked argyremia enabled us to discover the cause of the line and to differentiate the pigment from the confusing gum line of lead or bismuth. When the line is not present, the peculiar pallor of early argyria would be even more difficult to recognize. We suggest the spectrographic examination of blood for high and persistent silver content as a method of guarding against argyria during the use of silver arsphenamine, silver nitrate, mild silver protein, neosilvol and other silver preparations.

Finally, we wish to reiterate the word of warning in regard to the danger of internal silver therapy. Despite the possibility of sometimes decolorizing small areas of local argyria,¹⁶ the pigmentation of generalized argyria is so extensive that it may be considered permanent and beyond remedy. The controlled use of certain preparations cannot be opposed, but there are some silver treatments that are not only inefficacious but even lack the merit of being harmless.

SUMMARY

1. The spectrographic demonstration of marked argyremia, or high blood silver, permitted the detection of an unsuspected and obscure case of argyria, resulting from the oral administration of silver nitrate for gastrointestinal symptoms.

2. The blood silver was estimated spectrographically to be 0.05 mg. per hundred cubic centimeters; in normal blood, silver appears as a very faint trace or is absent, i. e., to an amount less than 0.0005 mg. per hundred cubic centimeters.

3. The persistence of the high blood silver for more than three months after exposure indicated a heavy deposition of silver in the tissues.

16. Stillians, A. W., and Lawless, T. K.: *The Intradermal Treatment of Argyria*, *J. A. M. A.* 92: 20 (Jan. 5) 1929.

4. Abnormally high silver was also detected in the urine, feces, cerebrospinal fluid, skin, dental tartar and probably saliva. The presence of the metal in the urine and feces demonstrated that silver was being partially eliminated from the body.

5. Only faint traces of silver were present in the blood and urine in definitely pigmented cases of argyria ten years or more after exposure; this showed the eventual departure of appreciable silver from the circulation.

6. The spectrographic determination of silver in the blood, skin and other parts of the body is an aid in diagnosing obscure argyria and in differentiating it from lead or bismuth intoxication.

7. The spectrographic determination of blood silver is suggested as a method of guarding against argyria in silver therapy.

8. A warning note is again sounded on the danger of internal silver therapy.

THE ORIGIN OF THE WHITE BLOOD CELLS

BRUCE K. WISEMAN, M.D.
COLUMBUS, OHIO

Since 1870, when hematology was first established as a branch of scientific medicine by the discovery of cells in the blood stream,¹ the polemics of the problem concerning these circulating units have centered about their origin. Each decade has witnessed an increasing volume of research and an even greater variety of interpretation in an attempt to establish some concept of the histogenesis of these cells on a sound and unassailable foundation. While complete success in reaching this objective has in no sense been attained, it nevertheless is profitable to analyze, from time to time, certain fundamental aspects of the problem which seem to be influenced or clarified by recent contributions in this field. Therefore, while recognizing the difficulties inherent in the problem and the necessity of altering interpretations from time to time as additional new facts become apparent, the present discussion will seek to analyze critically some of the more important concepts, with special attention to clarification of ideas in two directions; first, an elucidation of the position and of the separate identity of the lymphocyte in hematopoiesis, and, second, the newer evidence for the establishment of the independent origin of the monocyte from the reticulo-endothelial system.

THE EXISTING THEORIES IN EXPLANATION OF HEMATOPOIESIS

The demonstration of the mechanism whereby the white blood cells are formed depends, as in all biologic phenomena, in part on adequate experimental data and in part on interpretation. Only when the experimental evidence is adequate both in quantity and in quality does it become possible to make interpretations and draw conclusions that are convincing. So far as the origin of the white blood cells is concerned, it may be

said that the accrued mass of experimental fact has been adequate to convince the majority of hematologists on only three aspects of the problem: First, that the mother tissue for the formed elements of the blood is to be identified with a group of primitive cells designated by Aschoff and Kiyono² as the reticulo-endothelial system of fixed tissue cells. Second, that the cells of this structure by maturation and repeated division give rise to a generation of free cells with primitive nuclei and basophilic cytoplasm, which further divide and mature, thereby becoming ultimately the definitive cells of the circulating blood. Third, that the granulocytes and red blood cells exhibit different physical characteristics of the cytoplasm and nucleus, constituting maturative phenomena representative of a life cycle for each form. It may be added that the experimental data have not been adequate as yet to convince the majority of the investigators in this field on the following major points, which therefore have become highly controversial and subject to varying interpretations; first, that all cells of the reticulo-endothelial group are identical and therefore possess equal potentialities; second, that the free, primitive cell is identical with the blood lymphocyte and the latter is therefore always totipotent; third, that the life cycles of granulocyte and erythrocyte are reversible; fourth, that the monocyte is closely related to and probably identical with the clasmatocyte.

Chart 1 represents, by diagrammatic summarization, the principal theories held by the various proponents of the different schools of thought in explanation of the origin of the blood cells. The major points in conflict as well as those in agreement which were emphasized in the foregoing paragraph, are made quite evident by a study of this diagram. Extensive reviews³ which detail the experimental data that have given birth to these varying interpretations are very complete and no useful purpose can be served by repeating them here. Certain crucial aspects of the problem that have been referred to previously, however, deserve, and will receive, further elaboration.

THE SO-CALLED RETICULO-ENDOTHELIAL SYSTEM

Early in embryonic life, the diffuse mesenchyme consists of fixed star shaped cells and free mobile elements. The fixed mesenchyme (the endoderm and the ectoderm are not concerned in blood formation at any time) becomes differentiated into two cell types with different prospective potencies; the collagen-producing spindle-shaped elements become the fibroblasts of the adult tissues and probably lose all ability to reproduce cells other than themselves; the second type do not all differentiate but always there are some that retain embryonic characteristics throughout adult life. The latter elements are scattered throughout the loose connective tissue of the body and have been called resting wander-

ing cells,⁴ macrophages,⁷ and rhagiocrine cells,⁶ and are described in the serous membranes⁷ under the name of clasmatoocytes. They are particularly prominent in the spleen, lymph nodes and bone marrow, where they form a syncytium, and are in close relationship to the endothelium of the venous sinuses of the spleen, bone marrow, and lymph channels of the lymph nodes. At this point differences in interpretation have arisen. These specialized endothelial cells have been thought to be, in fact, flattened reticular cells identical with the syncytial primitive mesenchyme⁸ and therefore not true endothelial cells in the usual sense; others regard them as true representatives of endothelium,⁹ which in the bone marrow, liver, spleen and lymph nodes retain the angioblastic characters of the endothelium of the blood islands¹⁰ and therefore are embryologically distinct from and in no sense identical with the reticular cells.

The evidence for the identity of reticulum and endothelium, based on functional grounds, has been concerned largely with the reaction of these cells to vital dyes. On the introduction of vital staining, Ribbert¹¹ was able to show that the reticular and endothelial cells of the spleen, lymph nodes and bone marrow, the Kupffer cells of the liver and the reticular cells of the thymus and certain other tissues had the specific power to store lithium carmine. He noted that the general vascular endothelium took the dye either very faintly or not at all. However, the first investigator to formulate clearly the concept that these specialized endothelial cells were identical with the reticular cells was Goldmann,¹² who stained them intravitaly with pyrrhol blue, called them the pyrrhol cells, and identified them with the clasmatoocytes of Ranvier,⁷ the rhagiocrine cells of Renaut,⁶ the resting wandering cells of Maximow,⁴ and the adventitial cells of Marchand.¹³ Further interpretation was given by Aschoff and Kiyono¹⁴ in 1913-1914, when reporting on the vital staining characteristics of these cells in normal and pathologic tissues and describing their reaction in health and disease. They interpreted the relationship between these cells as constituting a tissue the component parts of which function identically so far as their reactions to vital dyes and the production of new cells are concerned. They expressed and emphasized this concept by inventing the term "reticulo-endothelial apparatus" to cover this system of cells.

Although the similarity of the reticular and endothelial cells in their reaction to vital dyes is admitted, yet there are many reasons based also on functional grounds that deny their identity. Aschoff himself in a later publication¹⁵ has noted that the reticulum and

endothelial cells of the lymph nodes behave differently toward particulate matter in that the latter show much more activity than the former in storing these substances. Cunningham¹⁶ found that the endothelium of the splenic sinuses and the reticulum cells of the pulp responded differently to injections of india ink in rabbits. Perhaps the strongest evidence for the dissociation of endothelium and reticulum has been presented by Doan,¹⁰ who was able to follow the independent regenerative reactions initiated by reticulum cells and endothelium on the hypoplastic marrow of starving pigeons, when the stimulus of an adequate diet was restored. The varying reactions of these cells to tuberculophosphate¹⁷ and to other lipid substances,¹⁸ in monocytic leukemia¹⁹ and in other pathologic states²⁰ furnish additional facts tending to warrant the dissociation of these two cells. Without further elaboration it seems certain from these facts that the common identity of the cells comprising the reticulo-endothelial system is extremely doubtful on embryologic, physiologic and pathologic grounds. The importance of establishing the

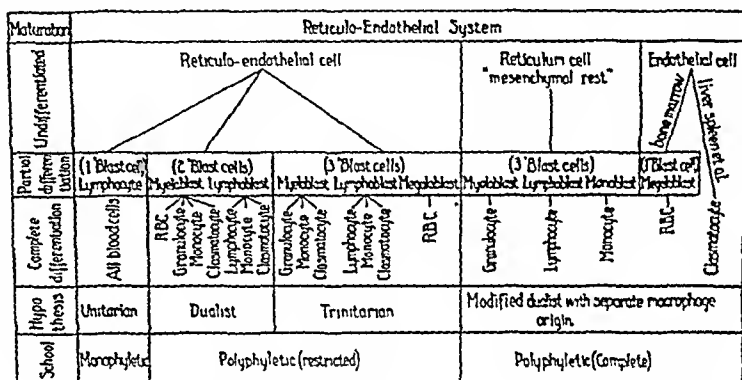

Chart 1.—This chart summarizes the principal points that are in conflict and in agreement between the various theories that have been advanced to explain the histogenesis of the blood cells. There are three levels of maturation that are common to all, in the first level primitive undifferentiated mesenchymal cells provide the blast cells of the second level, which in turn, by maturation and division, become the completely differentiated cells of the circulating blood, represented by the third level. The degree of polygenesis is determined by the number of partially differentiated (blast) cells that are believed to be necessary in order to render accordant the experimental facts and observations as interpreted by the various investigators which comprise the schools of thought shown in the lower portion of the chart. The principal difference, as indicated, is in the degree of prepotency ascribed to the blast cells, the unitarians feeling that a single common ancestor (the lymphocyte) may differentiate into any of the mature types of cells. Attributing lesser degrees of potentialities to this cell results in increasing degrees of polyphyletism, which in the extreme construction requires a separate blast cell for each of the circulating elements, and a separation of the reticulo-endothelial system of cells into its component units, each with different potentialities.

accuracy of this concept is fundamental to all hypotheses bearing on the origin of the blood cells and forms one of the basic differences between the proponents of the monophyletic and polyphyletic schools.

THE PROBLEM OF THE LYMPHOCYTE IN HEMATOPOIESIS

In all discussions involving the origin of the white blood cells, the rôle of the lymphocyte continues to occupy the central position about which all other concepts radiate. Lacking specific cytoplasmic substances that can easily be identified, such as granules, hemoglobin or vacuolar pattern, the separate existence of this cell type on a par with erythrocyte and granulocyte

intensity or absence of basophilia and the number of mitochondria in the cytoplasm have been found regularly to vary in association with the degree of maturity of the other blood cells. 3. Finally, the signs of cell death, consisting of a pyknotic nucleus and rupture of the cell membrane, when occurring in the absence of any features of immaturity and in juxtaposition to cells in the same blood smear which show no evidence of damage as a result of the technic of making the preparation, are generally accepted as representing the end of the life cycle.

Published observations describing the maturation of granulocytes have without exception subscribed to the observation, which is confirmed daily in every laboratory where blood cells are examined, that with increasing age there is a corresponding and parallel decrease in basophilic substance and content of mitochondria in the cytoplasm of these cells. In the oldest cells, corresponding approximately to the latter half of the Arneith range, both of these characteristics disappear entirely. The final phase of the life cycle represented by the "nonmotile" leukocyte of Sabin is easily demonstrated in any living preparation and shows unmistakable evidence of the spontaneous, senile cell death already noted. Visible nucleoli are never found in these cells except in those with minimal numbers of granules representing the less mature forms. Similarly, in the red blood cell series maturation of the cell with an increasing volume of synthesized hemoglobin and a corresponding decrease of basophilic and mitochondrial substance has also been adequately demonstrated and universally accepted as a phenomenon which reflects the aging process of this cell. The terminal feature in the life history of this cell is fragmentation, as demonstrated by Rous, a disintegration phenomenon equivalent in significance to the "non-motile" cell of the granulocyte series. So well established is the belief that basophilism of the red cell is a sign of youth that the presence of polychromatophilia and increased numbers of reticulocytes are used in every clinical laboratory as indexes of regeneration in this group of cells. As in the case of granular cells, nucleoli are found in the nuclei only in those types in which there is a minimum of specific substance in the cytoplasm and a maximum of mitochondria and basophilia, the type universally recognized as the immature form. Studies²⁷ have likewise indicated that the basic observations interpreted as criteria essential to the establishment of the age of granular and of red cells are true also for the maturation cycle of the monocyte. It may thus be concluded as a demonstrated fact that those cells of the circulating blood that exhibit the elaboration of specific cytoplasmic structures before functional maturity is attained also show change in the nonspecific substances (mitochondria and basophilia) that parallel immaturity. This concept is, of course, identical with that of a life cycle, as it is obviously impossible for cells to become progressively older without including this concept.

A consideration of these facts will make it apparent that any demonstration of an aging process (life cycle) for the lymphocyte must be secured by an analysis of the nonspecific characteristics of the cell. Logic also dictates that the finding of parallel decreases in mitochondria and basophilia in a series of these cells may

best be interpreted, by inference and analogy, as possessing a significance similar to that which has been proved for all the other blood cells. Previous work²⁸ has demonstrated that, in the lymphocytes, changes in mitochondria and basophilia parallel each other. Both of these characteristics range from a maximum concentration in cells in which the vesicular nuclei exhibit large nucleoli to minimal quantities in cells with nuclei devoid of visible nucleoli or to complete absence of mitochondria and basophilic substance in cells, which shows a pyknotic nucleus or a ruptured cell membrane. These facts were interpreted, therefore, as evidence of the existence of a life cycle for the lymphocyte comparable in most respects to those of the other cells of the circulating blood. To date, no other interpretation of these phenomena has been published.

Recent additional work in this laboratory has tended to strengthen this position.²⁹

The evidence given for the existence of a life cycle and separate identity, as developed in this experimental

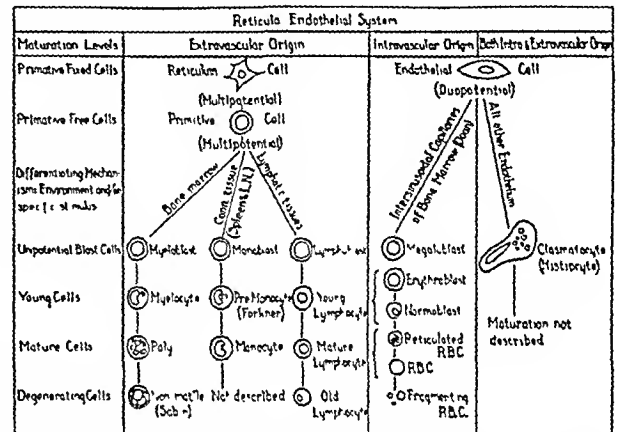

Chart 3—This chart is a graphic representation of the principal facts of blood formation as interpreted by proponents of the school of complete polyphyletism. This concept involves the separation of the reticulo-endothelial system into reticulum and endothelial cells, each with different prospective potencies. From the reticulum cell is derived a wandering cell of multipotential qualities, which in the presence of suitable stimulus and/or environment differentiates into one of the three blast cells of the white blood cell series. After a certain period of time, only one of these blast cells remains fixed, a only into more mature cells of its steps through the various phases of the red blood cell series are derive intersinusoidal capillaries of the bone marrow by the progressive steps illustrated. The endothelial cells throughout the reticulo endothelial system (including the bone marrow) are also the source of the large macrophage or clasmatocyte (histocyte) and may disquamate either into the tissues or directly into the blood. The relationship between the monocyte and the clasmatocyte is controversial and is explained in full in the text. Many adherents of the polyphyletic school of thought believe that the unitarians are confusing the primitive free cell of the former with the lymphocyte of the latter. If this is true, most of the differences between the two groups of investigators would be eliminated. The tissue lymphocyte of the unitarians would then be identical with the free primitive cell of the polyphyletists, and the blood lymphocytes would be identical save in potency. The proof for a tissue lymphocyte with multipotential qualities separate and distinct from a blood lymphocyte with highly restricted potencies would, in fact, erase most of the differences between these two groups of hematologists.

work and dependent on nonspecific characteristics, would appear to be the only avenue of approach available at this time to a solution of the problem of the separate identity for the lymphocyte.

THE ORIGIN OF THE MONOCYTE AND ITS RELATIONSHIP TO THE CLASMATOCYTE

One of the more difficult problems in the histogenesis of the white blood cells has been concerned with the origin of the monocyte. This no doubt has resulted

28. (a) Wiseman, B. K.: *J. Exper. Med.* 54: 271 (Aug.) 1931; (b) footnote 25a.

29. Experimental data substantiating this position are omitted in this publication but appear in the author's reprints.

27. Cunningham, Sabin and Doan²⁸ Doan, Sabin, Florence R.; Doan, C. A., and Forkner, C. F. *J. Exper. Med.* (suppl. no 3) p 52 (Dec.) 1930

largely from the difficulties (more apparent than real) in separating them from the lymphocytes on the one hand and from the clasmatocytes on the other. Largely devoid of specific cytoplasmic structures as observed in fixed sections, and possessing active phagocytic powers similar to the clasmatocyte, it is not surprising that the literature reflects the general confusion that relates to this cell. Originally described by Ehrlich as a "large mononuclear leukocyte" or "transitional form," the lack of definite conviction as to the separate identity of this cell that these terms suggest prevailed until Schilling³² and Naegeli³¹ established it as an independent cell strain. Its close relationship to lymphocytes in both origin and identity has been strongly maintained, largely on a basis of tissue culture work, by Maximow,³³ Weidenreich,³⁴ Downey,³⁵ Bloom,³⁶ Bergel³⁷ and others. Using similar methods of investigation, however, the Lewises,³⁸ Parker and Rhoades,³⁹ Carrel and Ebeling,⁴⁰ Hirschfeld⁴¹ and others have denied the conversion of lymphocytes to monocytes. To mention only a few of the widely divergent views, Turk⁴² thought them to be peculiar to the spleen and named them splenocytes; Möllendorff⁴³ derives them from the fibrocytes, Jolly⁴⁴ from the endothelium of the lymph node sinuses, Mallory⁴⁵ and McJunkin⁴⁶ from the vascular endothelium, Permar⁴⁰ from lung endothelium, Naegeli³¹ from the myeloblast, Cunningham, Sabin and Doan⁴⁷ and Forkner⁴⁷ from a specific stem cell, the monoblast.

Additional evidence bearing on this problem has been obtained by the analysis of the tissue reactions in two pathologic states. In the study of the chemical fractions of the tubercle bacillus isolated by Anderson⁴⁸ and biologically tested by Sabin and her group it was found that the lipid content of the bacillus possessed the specific ability to stimulate the formation of monocytes,⁴⁹ the protein and carbohydrate being entirely inert in this respect. It was possible, with the aid of the supravital technique in the areas in which acid-fast bacilli were located, to follow the maturation of typical monocytes from a primitive undifferentiated cell corresponding in all details with the monoblast of these and other investigators through to the epithelioid cell. It thus became evident that the fibroblast, endothelium and lymphocytes did not partake in the histogenesis of this cell when exposed to the specific monocyte-stimulating substances of the tubercle bacillus.

The establishment of monocytic leukemia as a specific pathologic entity by Reschad and Schilling in 1913⁵⁰ has made possible the study of a second patho-

logic state that has been especially important in contributing to the solution of the problem of the origin of the monocyte. A review of the literature shows that in almost every case of monocytic leukemia in which the pathologic changes of the tissue have been reported there has been a prominent hyperplasia of the "reticulo-endothelial system." Some of these authors have reported reticulum hyperplasia as predominating.⁵¹ In our experience with eight cases of this disease, we have been particularly fortunate in observing a case of chronic monocytic leukemia in which the tissue elements were not so densely packed as in the acute types, so as to defy the careful study of the origin of these cells. In this case it was possible to follow the steps of the maturation of this cell throughout its entire life cycle. These observations with photographs have been reported in detail elsewhere^{19a} so I will not repeat them here except to say that we can confirm the finding of reticular (not endothelial) hyperplasia described by some authors. We could also identify a specific blast cell corresponding to the monoblast of Sabin and follow its maturation into the typical blood monocytes. In this case no signs of hyperplasia of the various other elements, said to give origin to monocytes, were observed, although careful examination was made for them.

The evidence furnished by monocytic leukemia and tuberculosis, two conditions in which there is a specific stimulation of the monocyte strain of cells, has added considerable weight to the hypotheses of Sabin and her co-workers. It would therefore appear that the balance of evidence at this time strongly supports the conception that the origin of the monocyte is by means of a specific primitive stem cell, the monoblast, which in turn takes origin from the reticulum cell, as represented in chart 3.

Much less certain is the relationship of the monocyte to the true clasmatocyte or histiocyte. That there are rather marked morphologic differences in their reaction to the vital dyes neutral red and trypan blue is confirmed by every student of the subject. The monocyte is characterized primarily by a rosette of fine vacuoles about the cytocentrum, which always stain a uniform salmon pink. The clasmatocyte exhibits vacuolization of an entirely different character; the vacuoles are scattered throughout the cytoplasm without definite arrangement, vary greatly in size and display the varying pH of the intravacuolar fluid by reacting with the neutral red throughout its color range. It is also usual for the clasmatocytes to take up the trypan blue copiously, whereas the monocytes either refuse this dye completely or stain very faintly. Other minor differences pertaining to cytoplasm and nucleus tend to emphasize the morphologic dissimilarity, so that usually there is no difficulty in discriminating between these two cells in the supravital preparation.

Thus, while there can be no question concerning the separate identification of two phagocytic mononuclear cells based largely on the magnitude of their phagocytic powers, certain other facts make it more difficult to dissociate entirely their respective life cycles. Morphologically the shape, staining reactions and structure of the nucleus of the two cells are, if not identical, at least indistinguishable. Each has the same type of motility, subserves the same function and, in general, the two are

closely associated in most pathologic states in which the stimulus to phagocytosis is dominant. For example, in experimental studies of tuberculosis it has been shown that not only may both monocytes and clasmatocytes form epithelioid cells⁵² but giant epithelioid cells may be composed in part of monocytes and in part of clasmatocytes. Furthermore, the presence in the blood stream of both monocytes and clasmatocytes in large numbers as a feature of monocytic leukemia has been reported.⁵³ Finally it may be said that the entire evidence of tissue culture,⁵⁴ the work of the Clarks⁵⁵ using the web of the frog, the Sandison⁵⁶ window in the ear of the rabbit, and various studies of inflammatory exudates,⁵⁷ tends to make probable the concept that the clasmatocyte, at least in some instances, may be derived from the monocyte by hypertrophy and intense development of the phagocytic apparatus preexisting in a modified form in that cell.

This of course does not deny the proved fact, admitted by nearly all authors, that at least in the spleen, lymph nodes, bone marrow, omentum and liver clasmatocytes arise chiefly by mitotic cleavage of the endothelial cells of the reticulo-endothelial system located in those tissues. As recently pointed out by Doan,³⁰ it probably is best to regard the origin of the highly phagocytic clasmatocyte as threefold: from the endothelium, from monocytes and from preexisting clasmatocytes.

COMMENT

It is apparent from the foregoing survey that, while radically different positions may be and often are taken by certain extremists who have studied and contributed to the solution of the problem of the origin of the blood cells, the more important concepts involved in this biologic enigma are identical. All, or nearly all, students of the problem derive the white blood cells from the same mesenchymal structure. All, or nearly all, identify a primitive cell that becomes detached from this mother structure and serves as a blast cell for the subsequent derivation of the mature cells that are observed in the circulating blood. Certain groups (the so-called polyphyletic adherents) believe that there is a stage between that of the primitive free cell with multipotential characteristics and the fully differentiated blood cells in which certain immature cells with restricted potencies may be identified and be designated as specific blast cells for specific strains or lineages. Other groups (the so-called monophyletic adherents) deny the evidence for the existence of this intermediate stage of multiple blast cells, defending and supporting the position that the transition from immature to relatively more mature stages may be immediate without interposition of more involved phascs. The first group reserves the term "lymphocyte" for the indifferent round cell of the blood; the second group regards all indifferent round cells of mesenchymal origin, whether in blood or in tissues, as "lymphocytes," thereby including under this term the "lymphocytes" and all the blast cells of the polyphyletic proponents.

It is quite obvious that the various theories differ. if one considers only the essential major tenets of the

various schools of thought. only in determining how far back in lineage it is necessary to go before a common cell ancestor can be identified. Very few workers in this field, however they may differ in certain details, doubt the evidence for the existence of a single immature cell that has the inherent potencies for the production of any of the several white blood cells. Nearly all workers of both schools of thought believe that the direction of differentiation is determined or mediated by the influences of local environment and/or by a specific stimulus of unknown type.

The many and conflicting detailed explanations that have been advanced in an attempt to explain more fully the mass of experimental and objective observations pertaining to these cells in terms of life histories represent the transition phase of uncertainty between the well established facts of the present and the ultimate certainty of the future. The solution, in all its details, to the problem of the origin of the white blood cells which will be acceptable to all can be a realization only of the more distant future. It is probable that the development of present technical methods of investigation or the acquisition of new ones must precede the final disposition of the problem.

ABSTRACT OF DISCUSSION

DR. CHARLES A. DOAN, Columbus, Ohio: The results that have been presented today testify to the ingenuity and logical sequence of Dr. Wiseman's studies and to their potential clinical significance. With the establishment of criteria on which one may base the general conclusion that the lymphocyte is a separate and distinct entity with an independent life cycle has also come the means of appraising the efficiency of production of these elements. In our laboratory we are using every day the so-called Wiseman qualitative differential of the lymphocytes, because it gives a far more accurate interpretation of the activity of the lymphopoietic system than the quantitative data alone. Even as Arnetz and Schilling established the differential qualitative changes in the granulocytes, which are now indispensable to the intelligent understanding of the response to infection, so qualitative changes in the lymphocytes are proving to be far more important than any quantitative variations alone. We have already applied the principles outlined by Dr. Wiseman to a study of both experimental and clinical tuberculous disease. The various adenopathies and the leukemias involving the lymphatic system are being approached with such qualitative studies of the peripheral lymphatic elements with complete verification of the original hypothesis. Warburg studies of cellular respiration are now being correlated with definite age range variations in the lymphocytes, which bid fair to shed further light on their functional specificity and capacities. I believe that this recognition of the lymphocyte as a physiologic entity, established on a morphologic basis, has been a necessary prerequisite to the further study and solution of some of the many clinical problems involving these cells. Any evaluation of the blood picture in disease is now incomplete without the inclusion of the data on the qualitative appraisal of the lymphocyte.

Psychoses in Pernicious Anemia.—The actual incidence of psychotic changes in pernicious anemia is widely estimated by different observers, probably on account of the individual differences of opinion as to what constitutes a psychosis. Thus Cannon and Hayes in a recent textbook of psychiatry state that 5 per cent of patients with pernicious anemia develop distinct mental changes, while L  ufer found only one case of insanity in 190 cases of this anemia, and he quotes various authorities who have found the incidence even less than this. The differences in individual conceptions of psychotic changes become plain when the symptoms described as occurring are reviewed. —Parfitt, D. N.: Psychoses Associated with Pernicious Anemia, *J. THE EFFECT OF INITIAL TUBERCULOUS INFECTION ON SUBSEQUENT TUBERCULOUS LESIONS

J. ARTHUR MYERS, M.D.

AND

FRANCIS E. HARRINGTON, M.D.

MINNEAPOLIS

The effects of tubercle bacilli on experimental animals under various conditions have been reported on, but the lifetime of the animals used is so short compared with that of man and the resistance and susceptibility of the different species vary so much that it is impossible to determine in them all that is needed to be known about tuberculosis in the human body. It has been believed for some time that tuberculous lesions that appear in the bodies of children are of two types, namely, the first infection and the reinfection types, but very little work has been done to determine the effect of one on the other. In 1921 we undertook a longitudinal study of tuberculosis in the bodies of children. Since that time we have examined and studied 12,095 children and have observed each type of tuberculosis in its various stages of development, as well as the relationship of one type to the other.

FIRST INFECTION TYPE OF TUBERCULOSIS

Tuberculous lesions which develop in tissues that are not sensitive to tuberculo-protein are designated as primary lesions, first infection type of lesions, or, if in the lung, childhood type of tuberculosis. These lesions usually begin microscopically, and the first indication of their presence in the living body is the positive tuberculin reaction. Their location is never detected during life in the majority of cases. In a minority of patients, however, in whom the lesion is near the surface of the body, it may be located by the usual methods of examination. When in a part of the body which lends itself well to roentgen examination, such as the lung, it may become sufficiently large to cast a shadow that is visualized on the x-ray film. If it was observed early on roentgen examination, we have seen it pass through a stage known as the inflammatory or pneumonic stage, which persists several months to a year or more before resolution is complete. At some later time, varying from months to years, lime deposits may make their appearance in the region of the original primary lesion. One of the characteristics of the first infection type of tuberculosis is that the regional lymph nodes nearly always become involved and their disease passes through the stages already mentioned almost simultaneously with the first infection focus itself.

The diagnosis of the first infection type of tuberculosis is made primarily by the tuberculin test. The roentgenogram plays a minor rôle, while symptoms and physical signs are of little value.

Although we have been cognizant of the fact that the tuberculin test is not infallible and that there are on record a number of cases of frank tuberculosis, even

presenting tubercle bacilli in the sputum, which react negatively to the test, we feel that these are very exceptional cases and that, generally speaking, when the test is negative no tuberculosis exists. We are now using the new tuberculin known as purified protein derivative, prepared on Dorset's synthetic medium and purified by the method of Long and Seibert. This promises to be even more specific than old tuberculin. Thus, we look on the intracutaneous tuberculin test as a very fine screen and recommend it strongly as the initial phase of every examination for tuberculosis. It appears that a number of physicians have confused it with the subcutaneous test and regard the former as dangerous to use among patients who may have clinical tuberculosis. We have never seen any flare up of either a first infection or a reinfection type of tuberculosis that could be attributed to the intracutaneous test. Therefore, we consider it entirely without harm when properly administered. Dr. Edith Boyd of the department of anatomy kindly consented to make the statistical analyses of the incidence of reactions to the tuberculin tests with the technical assistance in computations of two Civil Works Administration workers.

Of the first 1,000 children examined, 41.6 per cent reacted positively to the test. As the epidermal (Pirquet) test was used at that time and only one test was given, we are of the opinion that our incidence of positive reactors was too low. This statement is based on subsequent comparisons between the epidermal and the intradermal tests. However, the incidence decreased until in 1933 only 23.6 per cent reacted positively. Thus, between 1921 and 1933 there has been a decrease of almost one half of the positive reactors (chart 1).

Apparently, there has been considerable decrease in the incidence of positive reactors among children in various parts of the country, as shown by Slater, Tice and Hruby, Chadwick, Peck and others. If the tuberculosis activities continue, it is obvious that the time is not far distant when the child who reacts positively to the tuberculin test will be a rarity. Already in some parts of the country instead of saying, as was formerly said, that approximately 95 per cent of girls and boys have been infected by the time they reach the teen ages, it is now possible to say that approximately 90 per cent of such girls and boys have not been contaminated by the time they reach this age period.

The next step in the diagnosis of tuberculosis in children is the roentgenogram of the chest. During the early period of our work at the Lymanhurst School we did not make roentgenograms as a routine, but as time passed we recommended stereoscopic films of the chest of every child. This included both negative and positive tuberculin reactors. At the close of ten years of work we had found so little evidence of tuberculosis in the chests of children who reacted negatively to the test that we decided to make films of only the positive reactors, being thoroughly cognizant of the fact that there would be an occasional failure. Moreover, we came to the conclusion that a single film of the chest suffices save for the exceptional case.

The value of making roentgenograms as a routine, regardless of the tuberculin reaction, is that other chest conditions may be detected. In chart 2 the incidence of abnormalities found in both the negative and the positive reactors is seen. This includes not only tuberculous lesions of first and reinfection types but also pleurisy, bronchiectasis, pneumonia, increased bronchovascular markings, cardiac changes, and the like.

Prepared with the aid of a grant from the Medical Research Fund of the University of Minnesota.

Read before the Section on Pediatrics at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934. From the Lymanhurst School for Tuberculous Children, Minneapolis and the Departments of Preventive Medicine and Internal Medicine, University of Minnesota.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints. A copy of the latter will be sent by the author on receipt of a stamped addressed envelope.

The roentgenogram of the chest in the diagnosis of the first infection type of tuberculosis is of far less value than was formerly believed. At one time there was a tendency to look on the child who had negative roentgen signs as one possessing no lesion of significance, but observation and analysis of cases soon led us to

Chart 1.—Annual incidence of positive tuberculin tests in 10,775 cases.

conclude that the roentgenogram is a very crude method of inspecting the body for first infection type of foci. Therefore we now rate the child who reacts positively to the tuberculin test and has negative roentgen signs as one with a definite focus of tuberculosis somewhere in the body. We no longer make exposures in lateral and oblique diameters in order to visualize deposits of calcium in the posterior mediastinum, nor do we make exposures through the cervical and abdominal regions to discover such deposits. The positive tuberculin test tells us that at least one first infection focus is present. The postmortem studies of Miller have shown that, when the first infection focus is located in the chest, the roentgenogram fails to reveal its location in 75 per cent of the cases. Other workers have found that it fails in even a higher percentage.

Observations on young adults who first become infected with tubercle bacilli have shown that they also develop a very benign first infection type of disease, just as is seen in the infant and child. This is one of the most encouraging facts that have been added to the knowledge of tuberculosis in recent times, since it completely breaks down the opinion so long held that the young adult who has not previously received a so-called protective dose of tubercle bacilli develops a rapidly progressive type of disease with the first infection. Thus, the program of prevention has been sound. The longer one can postpone the first infection with tubercle bacilli, the better. The ultimate goal is so to reduce the foci of infection that all persons will be able to pass through the span of life without contamination with tubercle bacilli. This the veterinarian has accomplished for cattle.

REINFECTION TYPE OF TUBERCULOSIS

The reinfection type of tuberculosis develops on tissue that is sensitive to tuberculin. In nature, so far as is known, such sensitiveness is produced in the

human tissues only by a first infection type of tuberculosis.

Reinfection foci have quite a different effect on the tissues than do those of first infection. While it is true that many of them are brought under control, it is also true that they tend to be destructive. They may be divided into two groups, acute and chronic. The best examples of acute reinfection types of tuberculosis are miliary disease and diffuse meningitis. Both develop on sensitive tissues and are highly destructive. Meningitis usually results from a focus in or near the central nervous system, which discharges bacilli directly or indirectly into the subarachnoid space. Miliary tuberculosis also results from a previously existing focus, often a tuberculous lymph node, which through rupture or otherwise discharges into a blood vessel or a large lymphatic duct, thus feeding the blood stream with tubercle bacilli. Without the previously existing focus that renders the tissues allergic and then feeds the blood stream with bacilli, miliary tuberculosis does not develop.

Good examples of the chronic form of reinfection type of tuberculosis are disease of the bones, joints and lungs. In the lungs the two main characteristics are fibrosis and cavitation. In the diagnosis of the reinfection type of pulmonary tuberculosis the tuberculin test is of little value, since it becomes positive with the development of the first infection type. However, among persons who have never previously been examined, the test is of great value. One must constantly bear in mind that it gives no information regarding the presence of a reinfection type of lesion. Symptoms and physical signs are usually late manifestations of the reinfection type of pulmonary tuberculosis. Here the roentgenogram is the most valuable diagnostic agent.

Chart 2.—Incidence of positive roentgenograms according to tuberculin tests.

Although this type of tuberculosis may be present in the lung a long time before it is sufficiently large to cast a shadow visualized on the x-ray film, it will be detected by the film in most cases earlier than by any other method of examination.

The question often arises as to which groups of children especially need roentgen examinations of the chest.

For several years at the Lymanhurst School we made stereoscopic films of all the negative as well as the positive tuberculin reactors but found that the test rarely failed when unmistakable tuberculous lesions were revealed by other phases of the examination. In fact, among 4,148 negative reactors there were only two who had definite evidence of the reinfection type of pulmonary tuberculosis. We concluded that, since only one case of frank reinfection type of pulmonary tuberculosis was missed by the tuberculin test in 2,074 examinations, we were hardly justified in using the taxpayers' money to make roentgenograms of the chests of negative reactors.

Under the age of 10 years, the chronic reinfection type of pulmonary tuberculosis is not a common disease. In fact, among the 12,095 children examined at the Lymanhurst School the reinfection type of pulmonary tuberculosis was found in sixty-two cases at the first examination. In this group, one was 6 years old, two were 7 years old, three were 9 years old, and the remainder were older. Thus, a patient with the reinfection type of pulmonary tuberculosis under the age of 10 years was found only once in each 2,016 examinations. Since roentgenograms are considered of value mainly in the detection of the reinfection type of disease in the lungs and since it was found so rarely in our group of children under 10 years of age, we have decided not to make roentgenograms of the chests even of the children who react positively but have not yet reached the tenth year unless there is some special indication. The cost is too great to justify the small finding. This also applies to private practice, among children of parents who cannot afford frequent roentgenograms. This finding seems to us to be of great practical significance, since a vast number of roentgenograms have been made and larger numbers are being recommended for children in this age period when pulmonary tuberculosis of the reinfection type is so rare. We find, however, that after the age of 10 years, the incidence of the reinfection type of tuberculosis in the lungs increases and is usually said to reach its peak at about the age of 25 years, after which it slowly decreases, but it still remains the first cause of death in this country until the age of 40 or 45 years. Therefore, in instructing parents of our clientele and in directing case-finding surveys and the like, we are able to call attention to the period of greatest danger during which roentgenograms should be made periodically. From the group we have observed, this period begins about the age of 10 or 11 years. In fact, in the remaining fifty-six children who were found to have the reinfection type of pulmonary tuberculosis at the first examination, the average age was 14.2 years.

Seventy-four children had nonpulmonary reinfection types of tuberculosis when they first came to us for examination.

At the first examination of 12,095 children the reinfection forms of tuberculosis were present in 136.

RELATIONSHIP BETWEEN THE FIRST INFECTION AND REINFECTION TYPES OF TUBERCULOSIS

The effect of the first infection type on the reinfection type of tuberculosis has in recent years been studied by five main methods.

The fourth method consists of observing groups of children or adults who are negative to the tuberculin test through periods of exposure, after which the tuberculin test becomes positive, then, over a period of years to determine the types of lesions which appear. This

has been carefully done in sufficiently large numbers of children, as well as students of nursing and medicine, that in the same bodies can be seen the complete evolution of tuberculosis from the time the tuberculin test was negative, through the exposure, the first appearance of the positive reaction, the later demonstrable first infection type of lesion on the x-ray film, and still later the reinfection type in the minimal, moderately advanced and far advanced stages.

Incidence of Reactions to Tuberculin Tests and of Clinical Tuberculosis on First Examination and on Subsequent Examinations *

First 4,000 Children Examined (1922-1926)

		0 died, nontuberculous cause.....	0.0 ± 0.00

* Percentage incidence, with its standard error indicated thus: 0.0 ± 0.00.

The fifth method consists of studying groups of children, both positive and negative reactors, over a period of years to determine which group provides more clinical cases of tuberculosis. This we have done at the Lymanhurst School for Tuberculous Children since 1921. Recently we have attempted to trace the children who have been examined in this institution. The accompanying table shows that, of 3,992 examined from 1922 to 1926, 1,816 have not yet been traced, of whom 819

were positive, 927 were negative and 70 were not tested when first examined. Of the 2,176 who have been traced since 1930, 1,017 had positive reactions, 1,058 negative, and ninety-nine were not tested on first examination. Of the 1,017 who had positive reactions, thirty-five already had the reinfection type of tuberculosis when first examined and forty-three others have developed this type of disease subsequently. Of the 1,058 negative reactors on first examination, five had the reinfection type of disease at that time and eight have developed it subsequently. Of the five who were negative to tuberculin but showed evidence of the reinfection type of disease on first examination, two had tuberculosis of the bones and joints, two had pulmonary tuberculosis, and one had both pulmonary and bone and joint disease. Of the eight who were negative when first examined but subsequently developed tuberculosis, six had pulmonary disease, one had pleurisy with effusion, and another had tuberculosis of the bone. Between the time we first saw them and when they were next seen with clinical disease, there was an average interval of six and one-half years. One of these children who was negative to the test in 1922 showed a positive reaction in 1926. At that time there was no evidence of clinical disease. However, in 1927 this child had tuberculosis of the sternum. Another child was negative in 1925; in 1926 the test had become positive but there was no evidence of clinical disease. In 1930 this child returned with pulmonary tuberculosis. Thus, an average period of six and one-half years existed between the time of our original examination and the development of pulmonary tuberculosis, which is ample time for children to become exposed, pass through the first infection type of disease and develop the reinfection type. Therefore, from the group of 1,017 who were originally positive to the tuberculin test, 4.22 per cent have developed clinical tuberculosis subsequent to our first examination, while 3.44 per cent had clinical disease on the first examination, making a total of 7.66 per cent who have died or already have clinical disease. Whereas, from the group of 1,058 who were originally negative reactors, only 0.75 per cent have developed clinical tuberculosis, while 0.47 per cent had clinical disease on the first examination, making a total of 1.22 per cent. Thus, the chances of positive and negative reactors having clinical disease or developing it in the next few years are seven to one in favor of the positive group.

If one divides the first group in the table into fourths, some rather interesting figures come to light. In the first fourth 3.73 per cent of the patients had the reinfection type of disease on first examination, while 5.8 per cent have developed it subsequently. Thus, 9.53 per cent of this group are already ill or have died from tuberculosis; whereas, of those traced who reacted negatively on first examination none had the reinfection type when first examined and only 1.08 per cent have subsequently developed it. The average age of the first fourth is now 20.8 years. Here the chances of positive and negative reactors having clinical tuberculosis or developing it by the time they have reached the age of 21 years is nine to one in favor of the positive reactors. Of the last fourth in the group included in the table 2.32 per cent had the reinfection type on first examination, while 3.19 per cent developed it subsequently. Among those traced who originally reacted negatively to the test, 0.66 per cent had the reinfection type of disease at the first examination and none has since developed

it. The present average age of the last quarter of the first group included in the table is 15.86 years.

Of those in the table who developed the reinfection type of disease subsequent to the first examination, forty had pulmonary tuberculosis. The average age at which this group of forty was diagnosed was 18.15 years. This finding would seem to be very significant when one considers that the mortality from tuberculosis does not reach its peak until about 25 years and continues to be the leading cause of death until 40 or 45 years. Therefore, there is ample time for considerable more destruction among this group of girls and boys.

The table shows that, of 3,998 children examined from 1926 to 1930, 1,014 have not yet been traced, of whom 511 were positive to tuberculin, 484 negative, and nineteen were not tested on the original examination. Of the 2,984 who have been traced, 1,169 had positive reactions, 1,781 had negative reactions, and thirty-four were not tested at the first examination. Of the 1,169 who had positive reactions, forty already had the reinfection type of tuberculosis when first examined and sixteen have developed it subsequently. Of the 1,781 negative reactors at the first examination, four had the reinfection type of disease when first examined and four have subsequently developed it. Thus, among those who had positive tuberculin reactions at the first examination, 3.42 per cent already had the reinfection type and 1.36 per cent developed it subsequently, making a total of 4.78 per cent who are ill or have died of tuberculosis, whereas among 1,781 who had negative tuberculin reactions at the first examination, 0.22 per cent had the reinfection type when first examined and 0.22 per cent later developed it, making a total of 0.44 per cent with clinical forms of tuberculosis. Here again one must take into consideration the average age of these children at the present time. In the first quarter of the second group in the table the average age is now 15.74 years; the second quarter, 14.19 years; the third quarter, 13.25 years, and the fourth quarter, 12.36 years. Thus, this group is well below the age when the reinfection type of tuberculosis becomes most destructive.

The table also shows that, of 4,088 children examined from 1930 to July 1934, 965 reacted positively, 3,107 reacted negatively, and sixteen were not tested. Of the 965 positive reactors, thirty had the reinfection type of disease at the first examination and three later developed it, whereas, of the 3,107 negative reactors, one had the reinfection type of disease at the first examination and one developed it subsequently. The children in the first, second, third and fourth quarters of this group are now respectively 11.93 years, 10.89 years, 9.49 years and 8.5 years of age. Thus, this group is far below the age when the reinfection type of tuberculosis becomes very destructive in the human body.

Dr. Edith Boyd has made the following explanation of the statistical constants and interpretation of the incidence of reactions to the tuberculin tests and the presence of clinical tuberculosis in the three groups included in the table:

When the difference between two percentage incidences is three times its standard error (standard error of first per cent \pm standard error of second per cent $2\frac{1}{2}$), such a difference would occur by chance for similar sized samples drawn from the same population only six in a thousand times. Hence, in conservative statistical practice, a difference which is three or more times its standard error is assumed to be significant; i. e., the samples probably came from different populations, and

one which is less than three is not significant; i. e., the samples probably came from the same population. In less conservative practice, the ratio of 2, which indicates five chances in a hundred, is taken as the dividing line.

Using the more conservative criterion, the percentage incidences in the table may be interpreted as follows:

In the first group of 4,000 children examined, the proportion of positive and negative tuberculin tests and no tests made are not significantly different in the untraced and traced groups; therefore, the traced group is probably a reasonable sample of the children at first examination. As would be expected, the 3.4 per cent incidence of clinical tuberculosis on first examination in the positive tuberculin group was significantly higher than the 0.5 per cent incidence in the negative tuberculin group. The latter probably represents faulty technic in administering the tuberculin or errors in reading or recording the test. In the group of children with positive tuberculin tests but without clinical tuberculosis on reexamination, eight years later 4.2 per cent had developed clinical tuberculosis, while in the comparable group with negative tuberculin tests only 1.0 per cent developed clinical tuberculosis.

In the second group of 4,000 children examined, the traced group contained an unduly low proportion of positive tests as compared with the untraced group, indicating some unaccounted for selective factor. Nevertheless, the proportion of clinically active cases in the groups with positive and negative tests at first examination remains the same as in the first group examined. The proportion of clinical cases occurring on reexamination among the group with positive tuberculin tests on first examination is significantly lower than in the first group, probably due to the short time interval between examinations.

In the third group of 4,000 children examined, when all children were traced about two years after the first examination, the percentage of clinically active cases in the positive cases on first examination remains the same as in the first and second groups while the incidence on reexamination is significantly lower than in the second group. In this total group the incidence of positive tests has been significantly reduced, so the number of cases of clinical tuberculosis in children at first examination has been reduced, even though the proportion in the positive tests remains the same.

In summary, during the past twelve or thirteen years the incidence of positive tuberculin tests in school children averaging 8 years of age has significantly decreased from 41.6 to 23.6 per cent. The proportion of the children with positive tests who had clinical disease on first examination has remained approximately 3.4 per cent. In the children with positive tuberculin tests on first examination, clinical tuberculosis had developed in 4.0 per cent of the first group reexamined about eight years later, in 1.4 per cent of the second group reexamined about six years later, and in only 0.3 per cent of the third group reexamined about two years later. In the children with negative tuberculin tests, less than 0.8 per cent developed clinical tuberculosis at a subsequent time. The incidence of clinical tuberculosis occurring in a group of children about eight years after their tuberculin tests were known to be positive is about five times as great as in a group known to have negative tuberculin tests.

Thus, from five methods of study used in recent years, we have come to look on the first infection with tubercle bacilli, as manifested by the positive tuberculin reaction, as a double health liability. First, because it has been shown that once tubercle bacilli are taken into the body and become encapsulated, they remain alive and virulent over long periods of time. Evidence has led to the suggestion that nature may defeat her purpose in that she first encapsulates with fibrous tissue and sometimes with calcium and even true bone but later resorbs this material and thus sets free the formerly imprisoned bacilli. Thus, apparently little or no control is possible over the foci of bacilli once they are allowed to develop in the human body. If one considers this fact alone and completely overlooks the possibilities of exogenous reinfection, there is enough evidence to sup-

port whole-heartedly the present campaign which aims at the prevention of the first infection of the human body with tubercle bacilli.

The second health liability is the allergy produced by the development of the first infection type of disease, which is manifested by the positive tuberculin reaction. Krause, Rich and others have called attention to the fact that allergy is a dangerous element from the standpoint of subsequent tuberculosis development. Rich says:

The damage done by allergy in this disease is very serious, indeed. A great part of the tissue destruction in tuberculosis is due to hypersensitivity to the protein of the tubercle bacillus. . . . Allergy converts the comparatively harmless protein of the tubercle bacillus into a virulent poison.

Wingfield says:

For a great number of our successfully treated cases one of the important factors in their prognosis, then, is their degree of sensitiveness. If this is high they are in greater danger than if it is low.

Chadwick says:

We know that the adult type of this disease can develop only in sensitized tissue made so by a preceding infection, and that the lesions caused by that early infection are often the source of the bacilli that produce the pulmonary tuberculosis of later years.

Thus, the tuberculosis control program which the medical profession has practiced in close cooperation with the National Tuberculosis Association and its component organizations has been sound, since its chief aim has been to protect the infant, the child and the adult against contamination with tubercle bacilli. We formerly thought it was good for a child to receive what we called a small dose of bacilli. At that time, we eased our consciences by saying that we were preventing massive doses but still allowing the child to receive small so-called protective doses. Obviously, any such teaching today would be looked on as absurd, since there is no measure or control of dosage and since even a small dose of bacilli, which leads to the first infection type of disease, produces a double health liability.

SUMMARY

1. The incidence of positive tuberculin reactors among children examined at Lymanhurst decreased 18 per cent from 1921 to 1934.

2. The first infection type of tuberculosis begins to develop on tissue that is not sensitive to tuberculo-protein. The immediate reaction is not specific but may be likened to that of a foreign body of the particulate type. The first infection type of tuberculosis observed from its early appearance over many years has not been seen to cause significant destruction. It is benign and is brought well under control in the majority of cases by the protective mechanism of the body. This is true not only in the bodies of children but also in young adults when they first become infected with tubercle bacilli.

3. The tuberculin test is the only fine screen available in the diagnosis of the first infection type of tuberculosis in children. It detects the presence of the disease long before other methods of examination are of any avail and in the majority of cases remains the sole diagnostic agent during life.

4. The roentgenogram fails to locate the lesion of first infection type in 75 per cent or more of the children who react positively to the tuberculin test. In the 25

per cent or less located by roentgen examination the lesions usually are not of clinical significance. Therefore the film gives no information of value beyond that provided by the tuberculin test. History of symptoms and physical examination are of little avail.

5. The reinfection type of tuberculosis develops on sensitized tissue, which meets it with a specific reaction. Good examples of the acute forms of the reinfection type of disease are tuberculous meningitis and miliary tuberculosis. Chronic forms are frequently seen in the lung parenchyma, bones and joints. Although chronic forms of reinfection type of tuberculosis may come under control, they have a strong tendency to progress and cause much destruction of tissues and result in illness and death.

6. The tuberculin test gives no aid in the diagnosis of the reinfection type of tuberculosis. However, this type of disease develops only among positive tuberculin reactors, made so by previous first infection type of disease.

7. The roentgenogram is the most valuable aid in the detection of the reinfection type of pulmonary tuberculosis. Usually it reveals the lesion months and even years before symptoms or abnormal physical signs are present and before tubercle bacilli can be detected by laboratory methods.

8. Children and young adults with negative tuberculin reactions so rarely show other evidence of tuberculosis as to make roentgenograms of all negative reactors unpractical as far as the finding of tuberculosis is concerned.

9. The chronic reinfection type of pulmonary tuberculosis is not commonly seen under the age of 10 years. In the present group it occurred only once in each 2,016 examinations. Therefore, to make roentgenograms of the chests of children under the age of 10 years is not practical when funds are limited, from either public sources or private families. After the age of 10 or 11 years, roentgenograms should be made periodically of the chests of all positive reactors.

10. The effect of the first infection type of tuberculosis on the reinfection type has in recent years been studied by five main methods:

(a) By animal experiments, which have shown that the animal tissues react to the first infection with tubercle bacilli as to a foreign body of the particulate type. After the tissues have been sensitized, however, reinfections are met by a specific reaction which often results in the destructive type of lesion.

(b) By postmortem examinations. When carefully performed, postmortem examinations have shown that a first infection type of lesion can nearly always be demonstrated in the bodies of persons who have had the reinfection destructive type of disease. This is true of acute forms of the reinfection type, such as meningitis and miliary tuberculosis, as well as chronic forms, such as pulmonary tuberculosis.

(c) By roentgen studies. Here is sought in frank cases of reinfection type of pulmonary tuberculosis roentgen evidence of the first infection type of disease. In from 50 to 75 per cent of cases the coexistence of the two types in the same chest is seen. This is very significant when one considers that the roentgenogram is a crude method of detecting the first infection type of lesion in the chest.

(d) By observing negative reactors after they become positive. This method has made it possible for one to observe the evolution of tuberculosis in the bodies of

human beings from the time when there is no evidence except the positive tuberculin test until the individual has far advanced pulmonary disease. In these cases the first infection type of disease always precedes the destructive clinical type.

(e) By observing children, both positive and negative reactors, over years to determine which group affords more cases of clinical tuberculosis. Of all the children traced who were previously examined at the Lymanhurst School, we have found that five times as many who had positive tuberculin reactions at the first examination have subsequently fallen ill as those who had negative reactions at the first examination. Among a group of children first examined in 1921 and 1922, of those who were recently traced, it was found that 9.53 per cent of the original positive reactors either had at the time of the first examination or have subsequently developed clinical tuberculosis, while among the negative reactors only 1.08 per cent have clinical disease. Therefore, in this group the chances of positive tuberculin reactors having or developing clinical tuberculosis in the next ten or twelve years is approximately nine times as great as among the negative reactors.

11. The first infection type of tuberculosis carries a double health liability, first, because in the foci of this type of tuberculosis tubercle bacilli remain alive and virulent over long periods of time and often for the lifetime of the individual. Whenever they are set free on allergic tissue they are capable of producing reinfection destructive type of disease, either acute or chronic, depending on the location and conditions. Second, because allergy results, which is a very dangerous factor, since it is responsible for a great part of the tissue destruction in tuberculosis and since it "converts the comparatively harmless protein of the tubercle bacillus into a virulent poison."

12. The program of tuberculosis control in this country is sound, because it aims to prevent the first infection type of tuberculosis from developing in the bodies of children and adults. To protect against this condition with its double health liability is a much sounder policy than any method aimed at immunization, which at best is questionable and which allows subsequent contamination.

ABSTRACT OF DISCUSSION

DR. HORTON R. CASPARIS, Nashville, Tenn.: There is no doubt that there must be a first infection before tuberculosis can develop. Ideally, the problem is to prevent the first infection; but from the practical standpoint Dr. Wallgren produces tuberculous infections in an attempt to immunize or carry a relative degree of immunity against subsequent infection. Practically all experimental data suggest that an infection that does not produce disease immediately carries with it a relative degree of immunity. Dr. Myers speaks of the double health liability in all of these infected individuals. There is no doubt about the first health liability, that is, that the presence of infection is potential tuberculosis, but as far as the second health liability is concerned, I think there is some question as to that. It seems rather remarkable that probably 30,000,000 or 40,000,000 persons have this infection with the sensitization of tissue, and that no more have manifested tuberculosis. It is evident that many from time to time receive subsequent inoculations of tubercle bacilli without manifesting any demonstrable reaction to those. In the cases that Dr. Myers showed, naturally those children who were infected when he saw them would be the group that would have more tuberculosis later on, because they were exposed to tuberculosis. I should like to ask him how much precaution was taken to prevent reexposure or reinfection in those positive

children. Any immunity that goes with tuberculosis is only relative. That can be overcome if a subsequent reinfection is sufficiently severe. It is my opinion that many persons have tubercle bacilli taken into their bodies, probably many times, without ever showing any manifestation of that reinfection.

DR. W. AMBROSE MCGEE, Richmond, Va.: Dr. Myers' study represents a large number of children observed over a long period of years. His ideas are more or less unusual and his excellent work should stimulate others either to prove or to disprove his conclusions. I am glad to hear Dr. Myers say that he has discarded the Pirquet tuberculin test in favor of the intradermal or Mantoux test. Contrary to some opinions, the intradermal test is usually positive even in such overwhelming infections as tuberculous meningitis. A practical and economical idea advanced by Dr. Myers is that the roentgen examination in children with negative tuberculin tests is not necessary. In those with positive tuberculin tests of the first type of infection also he has found the x-rays of little necessity. A few months ago I was able to make a comparative study of the Schilling differential count and sedimentation test in a few children with various stages of tuberculosis, from suspected cases to far advanced adult type. All of the children, of course, had positive tuberculin tests. The summary of the small material collected was that in cases of tuberculosis in which activity was apparent or far advanced the two tests paralleled each other, but in those of very slight activity or in the group observed as suspected tuberculosis the Schilling differential count was by far the better and was much more practical for children and more sensitive to even slight physical changes. If that test was used in a routine way by a competent hematologist it might aid one in dividing those children who have positive tuberculin tests in the first type of infection into two groups, those that by clinical observation and the Schilling differential fail to show evidence of any infection, and those that show some evidence of possible latent infection. From a broad view of allergy, it seems reasonable to feel theoretically that a first infection makes the child more prone to sensitiveness to the tuberculo-protein. The occurrence of only one reinfectious type of pulmonary tuberculosis in 2,306 cases certainly shows the low incidence in children who come within the age limits of pediatricians. The common idea that it was good for a child to receive a small dose of tubercle bacilli has certainly received a jolt, judging from Dr. Myers' observations. His conclusion that in reexamining tuberculous skin tested children the prognosis is much poorer when they had previously given a positive reaction appears in keeping with his statistics. If this finding is substantiated by subsequent observers, children with positive skin tests will have to be regarded as a double health liability. The children studied by Dr. Myers may have come from homes where tuberculosis was prevalent. If this is true, I wonder whether he has made a study of another group of children from surroundings more or less free from tuberculosis.

DR. J. A. MYERS, Minneapolis: In each case an attempt has been made to break contact just as soon as possible by isolating the parent or other source of infection. That is, an attempt is made to protect the child against subsequent exposure in every possible way. Of course, I have not succeeded in all cases. There is the occasional patient who absolutely refuses to protect the children and other members of the family. I have not questioned the statement that some immunity develops. I think its presence has been proved conclusively by a number of experimental workers. However, the allergy that nearly always develops is the dangerous factor, as it allows destruction to occur in the presence of immunity. I am inclined to believe from my observations that at least 10 to 20 per cent of children with positive tuberculin reactions at some time during life will suffer or die from clinical tuberculosis, for already more than 9 per cent of the positive reactors traced among the first 1,000 children examined have fallen ill, and several of them have died. It must be kept in mind that the average age of this group now is only 20.8 years, and that the peak of tuberculosis mortality is not reached in this country until about 25 years and that it remains high; in fact, it is the first cause of death in this country until about the forty-fifth year. Therefore, a good many years remain during which more children may fall ill with clinical tuberculosis.

Clinical Notes, Suggestions and New Instruments

THE BARBITURATES A SAFE PRELIMINARY MEDICATION FOR SURGICAL OPERATIONS

JAMES T. GWATHMEY, M.D., NEW YORK

Evidence that the barbiturates antagonize the toxic effects of procaine, both in the laboratory and in the clinic, indicates their preliminary medication for local and spinal anesthesia. The use of a preoperative barbiturate reduces the postoperative use of morphine by 28 per cent and vomiting by 15 per cent, as compared to the usual morphine preliminary, which requires 82 per cent postoperative morphine with 60 per cent vomiting.¹

Exactly which barbiturate is best or whether any of the barbiturates is better than the original barbital is, as yet, undecided. Theoretically, that particular barbiturate would be best which is most analgesic and is followed by the least nausea and vomiting. For children and also in obstetrics, nembutal is decidedly superior to any other barbiturate.

As a general proposition, all anesthetics should be so heavily premedicated (i. e., patient asleep) that the terminal anesthetic should never have to be pushed. The inhalation anesthetic should be supplementary to the preliminary medication, as this procedure reduces the amount of the inhalation anesthetic used and allows an increase in the oxygen, with pulse, respiration and blood pressure more normal than when any inhalation anesthetic is used without preliminary medication. Preliminary medication banishes fear and anxiety, thus conserving energy. Hooper and Gwathmey have shown that lung lesions occur with all inhalation anesthetics in laboratory animals not given a preliminary but do not occur when medicated.²

For these reasons, I have been using for some time for preliminary medication some one of the barbiturates. For the past two years I have been using sodium ipral. This is efficient in producing a quiet sleep, either before an inhalation or oil-ether colonic anesthesia. This special barbiturate seems to be unusually safe, as the following case will show:

A bottle of sodium ipral (the sodium salt of ethylisopropylbarbituric acid) containing forty-six tablets³ of 4 grains (0.26 Gm.) each was given to a nurse with directions to give three tablets to a patient (the usual dose) one hour before operation. This was done and the patient was asleep at the time of operation. Later, before returning the bottle, the nurse, in a despondent mood, on Monday, April 4, 1932, at 9:30 p. m., took forty-three tablets (4 grains each, 172 grains, or in all 11 Gm.) of sodium ipral, one at a time, with a swallow of water, using a glassful of water altogether. The tablets were taken as rapidly as possible in an estimated total time of fifteen minutes. Previously, at irregular intervals, the nurse had taken one tablet for insomnia and found that this produced a sleep of six hours with no after effect, but she had not formed a habit for the drug. The forty-three tablets did not seem to the nurse to put her to sleep quicker than the one tablet on previous occasions. She went to sleep in about the same way and time as with one. No throbbing of the heart or unpleasant sensation occurred.

She was discovered by friends the following day, April 5, at 1 p. m., sixteen hours after she had taken the 172 grains. Three tablets (12 grains, 0.8 Gm.) is the maximum dose as a basal induction anesthetic. Bernard Fantus states that the fatal dose of the barbiturates is from "fifteen to thirty times the therapeutic dose." Fifteen times three (the therapeutic dose) would be forty-five tablets, so forty-three tablets would not be a fatal dose, although the patient had every reason to believe it would be; i. e., the observation of the effects of three tablets on different patients. The fatal dose of Sodipral is unknown at this time.

I was called in consultation by the attending physician, as I had given the nurse the bottle of tablets. The stomach was washed out at 1:30 with warm water very thoroughly; respira-

3. A full bottle contains fifty tablets. I had used four tablets before giving the bottle to the nurse.

tion was considerably improved, although slightly labored but deep. The pulse was 84. The lid reflex was quite active. The color was good. She was now removed to Bellevue Hospital and sent to the emergency ward.

On admission, the pulse was 80. The temperature was 97 F. and rose to 103 the third day in the hospital but fell to nearly normal in a few days, with slight fluctuations afterward. The treatment following her admission and during the period of her unconsciousness consisted of colon irrigation, elysis, coffee enemas, and caffeine sodiobenzoate, 7 grains (0.46 Gm.) every four hours. The treatment followed precisely that outlined by Fantus.⁴ She regained consciousness the morning of April 9, four days after her admission to the hospital and five days after taking the forty-three tablets (172 grains).

The patient resumed nursing one month after her dismissal from the hospital. It is now over a year since this occurred. A thorough examination by her physician indicates no pathologic changes and, to all outward appearances, she is in perfect strength and health, and, best of all, has a cheerful and contented disposition.

133 East Fifty-Eighth Street.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed.

THERAPY OF GLAUCOMA

OUTLINE BY SANFORD R. GIFFORD, M.D.

Definition.—A sufficient increase in intra-ocular tension to damage the contents of the eyeball. Differentiation must be made between (a) Acute primary glaucoma, (b) chronic primary glaucoma, (c) secondary glaucoma and (d) absolute glaucoma.

Diagnosis.—The tonometer and the perimeter must be used as a routine whenever there is even a suspicion of glaucoma, which arises when in a person over 40 years of age there occurs a sudden failure in the amplitude of accommodation, a temporary loss of some or all vision, hazy or foggy vision, or the appearance of colored halos around artificial lights. In the normal eye the tension is between 15 and 25 mm. of mercury as measured by the tonometer (Schiotz).

ACUTE GLAUCOMA

Acute glaucoma is an emergency condition, most commonly arising during the latter part of the night with severe pain in the head, possibly nausea and vomiting, conjunctival congestion, "steamy" and anesthetic cornea, dilated and immobile pupil, discolored iris, rapid loss of vision, and hardness of the eyeball. Tonometric measurement should be taken at once and repeated at intervals to observe the effect of treatment. The patient should be hospitalized as soon as possible.

For differentiation from acute iritis, see "Therapy of Iritis."

Treatment aims at reduction of the intra-ocular tension to normal. This may be secured by:

1. *Miotics.*—Physostigmine Salicylate (1 per cent solution, prescription 1) should be instilled at once into the affected eye several times at intervals of a minute and then at half hour intervals. Morphine sulphate, 0.015 Gm., is injected hypodermically as soon as possible, for it at one and the same time increases the effect of the miotic and relieves pain.

PRESCRIPTION 1.—Physostigmine Eye Drops

R Physostigmine salicylate 0.10 Gm.
Saturated solution of boric acid 10.00 cc.

M. Label: One to two drops in eye every minute several times, then at half hour intervals (in acute glaucoma). This solution does not keep well; when it becomes pink or red it should be discarded.

2. *Saline Purgative.*—Also magnesium sulphate, 30 Gm. in concentrated solution (60 cc. of water), should be given at once.

3. *Hypertonic Dextrose Phlebotomy.*—The slow intravenous injection of from 250 to 500 cc. of 25 per cent dextrose solution should be instituted at once after admission of the patient to the hospital. Unless the tension subsides to the normal within a few hours, the patient should be taken to the operating room and receive a retrobulbar injection of procaine-epinephrine.

4. *Procaine-Epinephrine Retrobulbar Injection.*—To the syringe containing 1.5 cc. of a 4 per cent solution of procaine one adds 0.25 cc. of the Solution of Epinephrine and retrobulbar injection is performed, after preliminary application to the conjunctiva of 2 per cent butyn solution. It is not uncommon to find, ten or fifteen minutes after such an injection, the tension reduced by 10 to 20 mm., or even to normal. At the same time, good local anesthesia has been secured by it. Preoperative drastic reduction of intra-ocular tension is highly desirable to lessen the chance of hemorrhage following operation on the eye.

5. *Surgical Decompression.*—(a) Iridectomy: The eye should be held in downward rotation either by toothed fixation forceps which grasp the tendon of the superior rectus through the conjunctiva or else by a thread placed through this tendon. Incision is made with the keratome from 0.5 to 1 mm. back of the sclero-corneal junction, the blade being parallel with the iris surface. An incision 4 mm. long is sufficient. A small conjunctival flap may be made by picking up the conjunctiva with the point of the keratome before it is inserted, or a larger one by previous dissection with scissors. The iris is grasped at the pupillary border and drawn out of the wound. A radial cut is made in the iris at one side of the forceps. Then by gentle traction the iris root is separated from its attachment over an extent of 20 degrees. A second radial cut completes the iridectomy. The cut edges are replaced and the conjunctival flap is smoothed out with the spatula. One or two stitches in the conjunctival flap may be employed. The eye should be protected by a dressing and a rigid shield for a week.

(b) Paracentesis of the Eyeball: This procedure may be successful in aborting an acute attack when operation is impossible or must be delayed too long for safety. This simple paracentesis may be done at home and in the patient's bed with no other equipment than a syringe of 2 per cent cocaine solution, a speculum, fixation forceps and a small, sharp cataract knife. After physostigmine has been pushed for an hour, a marginal paracentesis is done and the physostigmine continued.

4. Fantus, Bernard: The Therapy of the Cook County Hospital: Barbiturate Poisoning, J. A. M. A. 103: 749 (Sept. 8) 1934.

CHRONIC GLAUCOMA

Chronic glaucoma may have no other subjective symptoms than a gradual loss of vision and contraction of the visual fields. There may be intermittent pain in one or both eyes, but this is often absent. Ophthalmoscopic examination shows cupping of the disks, and examination with the tonometer reveals a definite, but not extreme, increase in intra-ocular tension (from 30 to 45 mm. Schiötz).

1. *Miotics*.—These are successful in most cases in reducing tension to normal for a time. In a certain number of cases this effect may continue indefinitely. It is important, however, to check progress in each case by frequent field determinations and to remember that the tension varies during the day in glaucoma patients, so that one whose tension is always normal when seen in the office may have a higher tension at other times, especially during the night, which will cause gradual deterioration of the fields. Tension should therefore be taken at various times of the day and especially early in the morning before any miotics have been used. The danger of miotics is of overconfidence in their effect, and a patient using them must be under constant surveillance.

PRESCRIPTION 2.—*Pilocarpine Eye Drops*

R Pilocarpine nitrate 0.10 Gm.
Boric acid 0.20 Gm.
Distilled water to make 10.00 cc.
M. Label: Drop into eye from one to five times daily (in chronic glaucoma).

PRESCRIPTION 3.—*Pilocarpine Eye Salve*

R Pilocarpine nitrate 0.20 Gm.
Distilled water 1.00 cc.
Hydrous wool fat 2.00 Gm.
White petrolatum 7.00 Gm.
Mix with careful trituration and dispense in collapsible tube with eye tip.

Label: Apply to affected eye at bedtime (in chronic glaucoma). If collapsible eye ointment tube is not available, a glass rod may be used to apply salve to lower lid, which is then permitted to close. Gentle massage of lids helps to distribute ointment over the conjunctiva.

(a) Physostigmine 0.2 per cent (prescription 1, with reduction of alkaloid to 0.02 Gm. to each 10 cc.), or

(b) Pilocarpine 1 per cent solution (prescription 2); nitrate is preferable to hydrochloride, which is very deliquescent. Boric acid may be added for isotonicity and preservation of solution. Because of nocturnal tendency to rise of tension, an eye salve (prescription 3), which has a more enduring action, is preferable at bedtime.

2. *Epinephrine*.—Of the Solution of Epinephrine, about four drops is placed on a cotton pledget under the upper fold of the conjunctiva for four minutes. This may be useful in cases that are almost but not quite controlled by miotics. As there is some danger of an acute rise of tension caused by the epinephrine mydriasis, one should always precede it by a drop of 0.2 per cent physostigmine solution instilled three times at ten minute intervals and then every half hour for the next two hours or long enough to keep mydriasis from occurring, the danger of which is over in from six to eight hours. Miotics are then continued and tension may remain normal for longer than a week, in some cases for longer than a month. A number of cases may be kept under control for from eight to twelve months by repetition of the treatments, but in many cases later treatments are less effective and most cases finally come to operation. A few cases are unaffected by epinephrine and, when one attempt has failed, nothing is to be gained by further attempts. Epinephrine is contraindicated in types of glaucoma accompanied by inflammation. In glaucoma following cataract operation or

discission, however, the same objection does not seem to hold; and in a number of such cases it has controlled the tension until normal drainage has been reestablished without operative intervention.

3. *"Salt Free and Acid Ash" Diet*.—Elimination of sodium chloride from the diet, with the substitution of potassium chloride used freely as table salt, with a diet designed to have an acid ash, may cause edematous tissues to give up water in a manner sometimes surprising. Ammonium chloride is also given in doses of 6 Gm. a day to lessen further the alkali reserve. This plan may be carried out in those cases of chronic glaucoma in which the tension hovers slightly above normal in spite of miotics, as it may reduce tension to normal.

4. *Surgery*.—When the use of miotics and the general measures that have been mentioned fail to control tension and fields, one should employ operation. More harm is done in glaucoma by delaying surgery than by operations even when improperly performed. A filtering operation is the only form of procedure that offers an excellent chance of permanently reducing tension. Whether one chooses corneoscleral trephining, sclerectomectomy according to Lagrange, or iridencleisis will depend on one's training, but every ophthalmologist should be the master of at least one of these three procedures. Iridencleisis has the advantage of being less liable to certain well known complications than trephining. It is so much easier to perform that it should commend itself to the surgeon of limited surgical material. It seems ideal in buphthalmos. In cases of chronic glaucoma presenting a tension above 45 to 50 in spite of miotics, a recurrence of tension is more likely than after corneoscleral trephining and the latter procedure is to be preferred in such cases.

(a) *Trephining*: Fixation on the superior rectus is secured as for iridectomy. A large thin flap of conjunctiva is carried to the margin of the cornea and, if possible, a little beyond. This necessitates slight splitting of the corneal fibers. By means of a trephine, 1.5 mm. in diameter, an opening is made into the anterior chamber at the sclerocorneal junction and a bit of the iris is excised as it presents in the wound. The conjunctival wound is sutured.

(b) *Sclerecto-Iridectomy*: In this procedure, fixation and the preparation of a large conjunctival flap are the same as for trephining. Here the cornea is not split. The incision is made with a narrow Graefe knife, which cuts the sclera obliquely so as to come out 2 mm. behind the limbus, leaving a tongue of sclera. This is cut off with full curved scissors or a special punch. Iridectomy is performed, usually including a full sector of iris, and the conjunctival flap is carefully replaced.

(c) *Iridencleisis*: Fixation is done and a conjunctival flap made as for sclerecto-iridectomy. An incision 4 mm. long is made with the keratome 1 mm. back of the limbus. The iris is drawn out and one radial cut is made in the pupillary border. The piece of iris grasped by the forceps is allowed to remain out beneath the conjunctival flap, the inner pigmented side being turned outside. The straight conjunctival incision is closed with a running suture. (Another form of iris inclusion operation, "iridotaxis," is similar to the foregoing except that the iris is not cut, the pupillary border being left out under the conjunctival flap.)

SECONDARY GLAUCOMA

One speaks of primary glaucoma when no signs of previous inflammation or other pathologic changes are seen in the eye, and of secondary glaucoma when signs

of inflammation are found or when a dislocated lens, tumor, anterior synechia or other definite cause is present.

1. Whenever systemic infection can be demonstrated, whether it is "rheumatic," tuberculous or syphilitic, it should receive appropriate treatment alongside the therapy dictated by the dangerous rise of intra-ocular tension. Eradication of foci of infection is usually so disappointing in chronic glaucoma that only very obvious foci, such as dental root abscesses, should be taken care of. Mere suspicion is no indication here for removal of teeth or tonsils.

2. In iritis (q. v.) with secondary rise of tension, treatment with salicylate and foreign protein injections and elimination of the cause should form the background of the therapy, while the intra-ocular tension is kept within safe limits until the inflammation is controlled. As miotics are usually contraindicated in iritis, this may possibly be accomplished by ergotamine tartrate (gynergen), 0.25 mg. of which (one-half ampule) injected subcutaneously twice daily may succeed in reducing the pressure to the requisite degree. The effect must be carefully observed, as in certain cases it proves absolutely ineffective. Paracentesis, repeated after several days if necessary, is a safe and effective means of controlling tension for the brief period until treatment of the inflammation has become effective.

3. In cataract operation or discission, followed by glaucoma, epinephrine may prove of great value. Atropine should be avoided, Homatropine being used when mydriasis seems absolutely necessary. When the glaucoma resists this treatment, cyclodialysis is the operation of choice.

ABSOLUTE GLAUCOMA

When, possibly because of neglect of appropriate treatment, the eye has become stony hard, its sight lost, and it is a constant source of pain to the patient, enucleation of the eyeball is called for.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

RAYMOND HERTWIG, Secretary.

NOT ACCEPTABLE

SOUTHERN DAIRIES CREAMED BUTTERMILK WITH 150 VITAMIN D UNITS (STEEN- BOCK) (400 UNITS U. S. P.) ADDED PER QUART

The Southern Dairies, Inc., Asheville, N. C., submitted to the Committee on Foods a bottled pasteurized whole milk inoculated with a lactic acid producing culture, fortified with vitamin D (vitamin D concentrate prepared from cod liver oil) called "Southern Dairies Creamed Buttermilk with 150 Vitamin D Units (Steenbock) Added per Quart."

Analysis (submitted by distributor).—

Milk fat not less than 3.8 per cent.

Acidity as lactic acid 0.9 per cent.

Discussion of Name, Label and Product.—The name "Creamed Buttermilk" for a whole milk inoculated with a lactic acid producing culture misinforms the purchaser as to the true nature of the food. It is not a buttermilk with added cream as indicated. An appropriate name is "Lactic Acid Milk (Cultured)." Descriptive food names should be correctly informative and not misleading in any particular.

The label states the vitamin D content of the product but not the source of the vitamin. Since vitamin D from different

sources may have unlike nutritional values, the label should declare that the vitamin D was obtained from cod liver oil. No report of clinical studies on the human antirachitic value of this vitamin D fortified product was furnished. Without such studies, there can be no sound evidence on which to base any antirachitic advertising claims.

The distributor was advised of the recommendations and criticisms of the Committee but is unwilling to take action to correct the name and label, or determine the human antirachitic value of the food. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

DAWN FRESH MUSHROOMS

FANCY BUTTONS—PIECES AND STEMS—SLICED

Packer.—Michigan Mushroom Co., Niles, Mich.

Description.—Cooked mushrooms, whole, sliced, or pieces and stems, with added water, salt and citric acid (U. S. P.); the same as Excelsa Mushrooms, Fancy Buttons, Pieces and Stems, and Sliced (THE JOURNAL, Aug. 4, 1934, p. 342).

(1) LIBBY'S PETER PAN UNSWEETENED EVAPORATED MILK

(2) COMET UNSWEETENED EVAPORATED MILK

(3) TARGET UNSWEETENED EVAPORATED MILK

Distributors.—(1) Libby, McNeill and Libby, Chicago, and (2) and (3) Union Condensed Milk Company, Chicago.

Packer.—Libby, McNeill and Libby, Chicago.

Description.—Unsweetened, sterilized evaporated milk, the same as Libby's Sterilized Unsweetened Evaporated Milk (THE JOURNAL, June 13, 1931, p. 2037).

(1) HEBE STERILIZED UNSWEETENED EVAPO- RATED MILK

(2) MT. VERNON STERILIZED UNSWEETENED EVAPORATED MILK

Manufacturers.—(1) Hebe Company, Milwaukee and Seattle, and (2) Mt. Vernon Milk Company, Seattle, subsidiaries of the Carnation Company, Oconomowoc, Wis.

Description.—Unsweetened, sterilized evaporated milk, the same as Carnation Sterilized, Unsweetened Evaporated Milk (THE JOURNAL, June 14, 1930, p. 1919).

(1) QUAKER BRAND UNSWEETENED BAKING CHOCOLATE

(2) NARRAGANSETT BRAND COOKING CHOCOLATE UNSWEETENED

Distributors.—(1) Lee & Cady, Detroit, and (2) Narragansett Wholesale Grocery Co., Providence, R. I.

Packer.—Moffat, Inc., Boston.

Description.—Ground cacao nibs or "chocolate liquor" in cake form. Same as Moffat Cooking Chocolate Unsweetened (THE JOURNAL, Jan. 20, 1934, p. 213).

Claims of Manufacturer.—Conforms to the United States Department of Agriculture definition and standard.

SATURDAY, NOVEMBER 17, 1934

UTILIZATION OF VITAMIN A
AND CAROTENE

Among students of metabolism it is an axiom that food materials or therapeutic substances are not effectively in the body until they have passed from the gastro-intestinal tract into the blood or lymph. Many factors ordinarily exert an influence on materials in the intestinal tract, and absorption and subsequent utilization are to a great extent dependent on them. The action of the digestive enzymes is, in the main, looked on as a sine qua non to normal nutrition; yet hydrolysis by the proteases frustrates the oral administration of insulin. In the presence of acid the absorption of calcium is favored, whereas an alkaline reaction in the intestine tends to precipitate calcium not only as the phosphate but also as insoluble soaps of the fatty acids of the food, thus doubly robbing the body of dietary essentials. In the opinion of certain students of the subject, the hypothesis that beriberi is of infectious origin rather than caused by a deficiency of vitamin B can be disposed of by pointing out that gastro-intestinal disturbances themselves infectious prevent the usual absorption of foods containing vitamin B, thus obscuring the real cause of the disease. Again, it has been shown¹ that in the absence of bile from the intestine there is apparent difficulty in the absorption of vitamin D. In rachitic animals with obstructive jaundice, cod liver oil fails to promote calcification.

In a recent study, Dutcher and his associates² have added to the foregoing thesis in considerable detail. In an attempt to elucidate the reported difference between the utilization of vitamin A from butter and that from cod liver oil in the presence of liquid petrolatum, they studied the behavior of the pigment carotene under similar circumstances. Groups of experimental animals were given adjusted quantities of liquid petrolatum together with various amounts of butter fat, carotene, cod liver oil and an extremely potent concentrate of

cod liver oil. When cod liver oil was given in minimal quantity together with a relatively large amount of liquid petrolatum, utilization of the vitamin A was inhibited; however, increasing the amount of cod liver oil led to favorable results. The potent concentrate of cod liver oil was well utilized despite the liquid petrolatum. When butter was the source of the vitamin A potency, liquid petrolatum exerted a retarding influence on its absorption to an appreciable extent. With the pigment carotene providing the sole source of vitamin A, there was a marked retarding effect on its utilization. These observations are generally in accord with other observations³ made under somewhat different conditions.

In an effort to determine the mechanism whereby the utilization of carotene is prevented by liquid petrolatum, an antioxidant was added. The results indicated that there was no destruction of the pigment by oxidants in the liquid petrolatum. By careful extraction of the feces of the experimental animals to which liquid petrolatum and carotene had been fed, the pigment was recovered, indicating that the utilization of carotene was almost completely prevented by the liquid petrolatum. In like manner it was demonstrated that the vitamin A concentrate did not appear in the feces.

The investigation just described clarifies a confused situation. There is little doubt that vitamin A can be absorbed from the intestine despite the presence of liquid petrolatum. On the contrary, the pigment carotene, which usually accounts for the vitamin A potency in plants and plant products and which in the animal body is transformed to vitamin A itself, is absorbed from a solution in liquid petrolatum to little if any extent. The previous confusion with reference to butter arises from the fact that both carotene and vitamin A occur in butter and the relative quantities vary.⁴ Liquid petrolatum will therefore vary in its effect on different samples of butter. The action of liquid petrolatum on carotene is merely one of preferential solvent; the pigment is apparently more soluble in the liquid petrolatum than in the lipides of the intestinal and pancreatic juices or the lipides of the food residues.

These studies emphasize the unique contrast in external behavior between two structurally related compounds which, once they are inside the body, behave identically. They should also help to clarify the status of liquid petrolatum, which has had a considerable vogue among physicians as a therapeutic agent. In practice, as has been pointed out,⁵ the usual manner of taking liquid petrolatum, i. e., apart from a meal, virtually eliminates the danger of loss of vitamin A or its precursor (carotene) by the mechanism here discussed.

CHIROPRACTORS AND NATUROPATHS DEFEATED

Chiropractic and naturopathy received a noteworthy setback, November 6, when the people of Arizona, California and Oregon decisively defeated at the polls measures for the aggrandizement of those cults submitted under the initiative system of legislation.

In Arizona the naturopaths wanted an independent naturopathic examining and licensing board. They wished to have naturopaths exempted from the requirements of the basic science law and authority for every licensed naturopath to exercise every right and privilege given by law to any practitioner of the healing art.

In California a schism in the chiropractors of the state sought by an initiative measure to add to chiropractic prerogatives a monopoly of the right to practice physical therapy, by providing for the issue to licensed chiropractors only of licenses to practice physical therapy, authorizing the holders "to practice obstetrics; to use, prescribe and practice prophylactic hygiene and sanitation and dietetics, including, in any form, herbs, oils and all animal and vegetable foods; and to use all systems, methods or instruments in diagnosis, including the use of roentgen rays." Under the chiropractic initiative all licensed chiropractors in the state were to constitute a public corporation, with officers elected by the members, with power to regulate chiropractic practice, to levy dues on its members and to discipline its members. The dominant group of chiropractors in the state publicly denounced the measure, saying that the chiropractic initiative measure of 1922 had vested in them all authority necessary to enable them to practice legitimate chiropractic. Another California naturopathic initiative sought to establish naturopathy by law as a distinct school of healing, with its own independent examining and licensing board. It proposed to organize all licensed naturopaths in the state into a self-governing public corporation. Naturopathy was defined by the measure as including "physiotherapy, physical therapy, phytotherapy, biochemistry, the use of antiseptics, anesthetics, applied therapeutics and prophylactic hygiene and sanitation; the science and art of diagnosis, which enables the naturopathic physician to direct, advise, prescribe, dispense or apply food, water, roots, herbs, plants, oils, lights, heat, color, exercises, active and passive, manipulations, correcting vital tissue, organs or anatomical structures by manual, mechanical or electrical treatment, instruments and appliances, x-ray, or any and all other natural agencies that have been used in the past, that are now in use, or that may be used in the future, to assist nature in restoring a physiological and psychological interfunction for the purpose of restoring and maintaining a normal state of health, mentally and physically."

In Oregon, chiropractors and naturopaths already have their independent examining and licensing boards. A basic science law that went into effect Jan. 1, 1933,

however, seems to have given alarm to chiropractors and naturopaths generally, and particularly to a struggling chiropractic school in the state, whose graduates, under the basic science law, were threatened with the necessity of having to show that they had been adequately instructed in anatomy, physiology, chemistry, pathology and hygiene, before an independent board, before they could appear before the chiropractic board for examination. The chiropractors of the state therefore combined with the naturopaths in proposing as an initiative measure an amendment to the state constitution that would have abolished the examinations in the basic sciences under the basic science law. The measure was so worded as to permit the governing board of the chiropractic and naturopathic bodies to enlarge the scope of practice of their adherents in such a way as to permit them to use drugs and possibly even to enter into the general practice of obstetrics and surgery.

Through the effective work of the state medical associations of Arizona, California and Oregon, and with the aid of many public spirited citizens both individually and in organizations, the people of these states were kept informed as to the dangers threatened by the proposed initiative measures. As has been mentioned, decisive defeats resulted in each state. The people of Arizona, California and Oregon are to be congratulated on maintaining their standards of medical care. Apparently the majority of the voters recognized the necessity for protection against ignorance, superstition and incompetence in medical care.

RAMÓN Y CAJAL

Spain's great medical scientist Ramón y Cajal has died, leaving an illustrious group of students to carry on in the Instituto Cajal in Madrid. Born in an isolated mountain village, Cajal inherited a strong will from his father, who was a surgeon, and a talent for art, music and philosophy. Too early the father showed a determination to develop in the son a talent for medicine, and in several attempts under coercion the young son did not succeed. A love for drawing and painting occupied much of his time, yet in school his teachers declared that his drawings had little merit. They found him indifferent and said that he had no memory. Twice he was removed from school altogether and apprenticed to a barber and a cobbler. Then he became absorbed in painting and in the perusal of novels. The despairing father again undertook to start Ramón on the way to a medical career, teaching him osteology. The artist in young Ramón took to making pictures of bones from every angle and at last he became a skilled anatomist. To these modest lessons on human bones Cajal attributes his ultimate development into a morphologist. He then went to Zaragoza in Aragon, where the father had been appointed professor of anatomy in the university and Ramón, without any indications of brilliance, obtained a medical degree in

1873. As a student at Zaragoza, he acquired a mania for gymnastics, developing his own exercises, to which he devoted much time. His physical prowess, no doubt, helped him gain admittance to the medical corps of the Spanish army and he sailed for service in Cuba in 1874, to be assigned to an isolated infirmary at Vista Hermosa, where he soon acquired malaria and dysentery. Cajal was very sick when his resignation was accepted in 1875 but he arrived home in Zaragoza improved by the voyage and went to Madrid to be examined for a doctorate. There he first saw a microscope. He was appointed in turn an assistant demonstrator at the University of Zaragoza, to the chair of anatomy and as director of the anatomic museum. He developed pulmonary tuberculosis, which necessitated living outdoors most of the year 1878, and in 1879, against the advice of friends, he married on a small salary. Garrison's translation of Cajal's account of meeting his future wife illustrates his simplicity and candor:

Returning one evening from a walk to Torrero, I encountered a young girl of modest appearance, accompanied by her mother. Her blushing, springlike face suggested Raphael's madonnas or, better still, a German colored engraving of Marguerite in Faust. Attracted no doubt by the sweet, pleasant disposition apparent in her features, her slender figure, her large green eyes veiled by long lashes, her abundant hair, I was even more impressed by the air of childlike innocence and melancholy resignation which emanated from her whole being. Unseen, I followed the young girl to her home, learned that she was the orphaned daughter of a modest employee and enjoyed a reputation for honor, modesty and domestic tastes. I made her acquaintance and after a time, against the collective advice of my family, married her, not without due consideration of the mental characteristics of my fiancée, which were complementary to my own. My resolution was discussed by acquaintances in clubs and cafés as an act of madness: Poor Ramón is lost forever. Goodbye to study, science and general ambitions. . . . And yet, although eulogies do not flow readily from my pen, I take pleasure in saying that, with beauty which seemed predestined to shine in promenades, visits and receptions, my wife cheerfully condemned herself to the obscurity of my lot, remaining simple in her tastes and with no other aspirations than tranquil contentment, order and system in the management of the home, and the happiness of her husband and children.

In 1884 Cajal accepted the chair of anatomy at Valencia, where an epidemic of cholera developed the next year. He was the first in Spain to establish by a staining method of his own the relation of the comma bacillus to cholera. He was presented with a fine microscope by the Central Committee, and with it he began to investigate the degenerative processes in the protoplasm of the comma bacillus. Now at the age of 32, he fitted up a small laboratory in his home and added to his meager salary by coaching graduate students. A neuropsychiatrist of Madrid, Dr. Luis Simarra, told Cajal of Golgi's chrome silver stain, which method Cajal improved and applied to the entire nervous system. His study of the histology of the nervous system really began in 1887 with his transfer to the chair of anatomy at the University of Barcelona, where he began to publish his microscopic studies and

then to send communications to foreign journals. He was invited to discuss his work before the members of the German Anatomic Society in Berlin in 1889. They were skeptical at first, but after Cajal's demonstration of beautiful preparations of axons of granule cells of the cerebellum, of the bifurcations and ascending and descending branches of the sensory spinal roots, and of the long and short collaterals of the tracts of the white substance and of the terminations of the retinal fibers in the optic lobes, Kölliker, the patriarch of German histology, introduced him to many notable German histologists and embryologists and returned to Würzburg to try out Cajal's methods. Kölliker was able to substantiate Cajal's work. Having established a wide reputation, he was invited to become a professor at the University of Madrid in 1892, where he undertook arduous investigation incompatible with the social distractions of Madrid. In 1894 Cajal delivered the Croonian lecture before the Royal Society of London, and honorary degrees were conferred on him by Oxford and Cambridge. Although his country had just been at war with the United States, he was invited in 1899 to Clark University for the decennial celebration, where he gave three lectures on "The Comparative Study of the Sensory Areas of the Human Cortex." These lectures are important contributions to the subject. At this time, Garrison¹ says, Cajal was a handsome figure with the abstract mien of a laboratory worker, in the prime of life and of international reputation. The scientific world now acclaimed him. Cajal had already gained the Rubio, Fauvelle and Martinez Molina prizes. He was awarded the Moscow prize at the International Congress of Medicine in Paris in 1900, and in 1904 the Helmholtz medal of the Royal Prussian Academy. In 1906 Cajal was summoned to Stockholm to receive the Nobel prize, jointly with Golgi. The subject of his address on this occasion was "Structures et connexions des neurones." Although now at the pinnacle of scientific recognition, his life work was only well begun. Cajal advanced now, Addison² says, from methods for demonstrating the neurofibrils within the neurons into new methods for showing the structure of the neuroglia more definitely. His pupils, among whom have been such men as Nicolas Achucarro, Pio del Rio Hortega, Francisco Tello, de Castro, Villaverde, Sanchez and Llorente de No, have exhibited great enthusiasm. The Spanish School of Neurohistology has contributed as much to the knowledge of the neuroglia as of the neurons. In 1906 Spain offered Cajal the ministry of public instruction, which was declined. In 1913-1914 he published his great work on degeneration and regeneration of the nervous system. Garrison has listed chronologically, beginning in 1880, the scientific achievements of Cajal.

1. Garrison, F. H.: Ramon y Cajal, *Bull. New York Acad. Med.* 5: 483 (June) 1929.

2. Addison, W. H. F.: Ramon y Cajal—An Appreciation, *Scient. Monthly*, August 1930, p. 178.

His masterpieces are his encyclopedic treatises on neurohistology (1897-1904) and on degeneration and regeneration in the nervous system (1913-1914). His actual contribution is the ultimate developmental and structural basis of the dynamics of the neuron, of transmission of impulse, of localization of function, and of degeneration and regeneration of the neurons and axons of the nervous centers.

Cajal the philosopher is at his best in *Chácharas de Café*, a series of aphorisms and anecdotes to which editorial notice was given in *THE JOURNAL*³ in 1921, and in which he said:

Every gratuitous burden of responsibility is essentially immoral.

A woman venerates her parents, esteems her husband but adores only her sons.

When I clapped for the waiter in a café, it was greeted by the wretched pianist as applause.

We disdain and hate from lack of self comprehension and we understand in proportion as we study ourselves.

Try to honor your children lest they dishonor you.

Those who have not been a little wild in youth are in danger of being so in age, excepting always the mentally defective, the weak willed and the prematurely old.

The highest happiness almost always coincides with forgetfulness of ourselves and of others. This beatific alienation of frivolous or disagreeable things is attained when we ask our servant: Have I eaten?—an unequivocal criterion of vocation.

Do you wish to be invisible to men? Be poor. To women? Be old.

In the future, children will be for the poor a resource, for the plutocrat a mode of ostentation, for the bureaucrat and small rentist a sacrifice.

Current Comment

PROTECTION AGAINST DUSTS

As a direct result of the work of such men as Gardner at Saranac Lake, Sayers of the U. S. Public Health Service, Lanza of the Metropolitan Life Insurance Company and Pancoast of the University of Pennsylvania, the clinical and pathologic aspects of the silicosis problem are slowly but surely becoming clarified. In the prevention of silicosis in the mining industry, the physician has long advocated less dust in the air breathed, but the practical mining man has been unable to achieve adequate cleanliness and still continue his industrial operations. In many phases of mining and other industries, however, signal advances have been made in dust control. The Bureau of Mines has always been at the front in the formulation of such improvements. Through its Pittsburgh experiment station the Bureau of Mines now offers a new routine¹ for the testing and certifying of respirators or dust masks for protection against the inhalation, by workmen, of harmful dusts, fumes and mists. It will be recalled that it was this station which pioneered in the development of the U. S. Army gas mask at the time of America's entry into the war. Since then the bureau has formulated a series of schedules for testing and

certifying industrial gas masks. So useful have the certifications become that purchasers are loath to buy masks which lack this certificate. Until the publishing of the new schedule 21 there was no federal or private testing code to which the manufacturer of respirators could turn for certification of his product. The result has been an unfortunate promiscuity in the manufacture and sale of inferior protective devices. The new schedule gives a series of examinations and tests sufficiently exacting for the most fastidious. The purchaser of industrial respirators for protecting workmen will do well to demand articles with the Bureau of Mines' stamp of approval.

Association News

THE CONFERENCE ON ECONOMIC SECURITY

The Committee on Economic Security announced a national conference on the subject to be held in Washington, D. C., November 14, at the Mayflower Hotel. Round table conferences were held on unemployment insurance with Prof. Joseph H. Willets, University of Pennsylvania, presiding; on child welfare with Grace Abbott, University of Chicago, presiding, and on provision of employment. There were also conferences on old age security and on medical care. The conference on medical care was under Livingston Farrand, president of Cornell University, as presiding officer, and the discussion was led by Drs. Henry A. Luce, Detroit; Nathan B. Van Etten, New York; George E. Follansbee, Cleveland, and Mr. Michael M. Davis of the Julius Rosenwald Fund, Chicago. A reception by the President for the conferees was held at the White House at 5 o'clock and the conference was concluded with the dinner at 8 o'clock, before which Harry L. Hopkins, Federal Emergency Relief Administrator, and Frances Perkins, Secretary of Labor, were speakers.

Following the conference on November 14 the various advisory boards met on November 15 and 16. The advisory board on medicine was under the chairmanship of Dr. Harvey Cushing, the members included being Walter L. Bierring, Des Moines, Iowa; James Alexander Miller, New York; Robert B. Greenough, Boston; James D. Bruce, Ann Arbor; Rexwald Brown, Santa Barbara; Thomas Parran, Albany; George W. Crile, Cleveland; Stewart R. Roberts, Atlanta, and George M. Piersol, Philadelphia.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Abstract of Minutes of Business Meeting Held at Chicago, October 27

The Council members present were Drs. Ray Lyman Wilbur (chairman), Reginald Fitz, Merritte W. Ireland, Charles E. Humiston, Frederic A. Washburn, J. H. Musser, Fred Moore and the secretary, Dr. William D. Cutter. In attendance also was Dr. Walter L. Bierring, President of the American Medical Association. Members of the Council's staff included Drs. Fritjof H. Arestad, Oswald N. Andersen, Carl M. Peterson, H. G. Weiskotten and Mr. Homer F. Sanger.

The following resolutions were adopted and other business transacted as indicated:

Resolved, That the minutes of the business meeting of June 10, 1934, be approved.

Resolved, That the minutes of the meeting of the Council's Subcommittee on Medical Education, held in New York, Sept. 15, 1934, be approved.

The proposal to send a communication to all hospitals approved for the training of interns, notifying them of the resolution adopted by the House of Delegates at the Cleveland session by which membership on the staffs of such hospitals

3. A Spanish Medical Philosopher, *Current Comment*, J. A. M. A. 76: 595 (Feb. 26) 1921.

1. Procedure for Testing Filter-Type Dust, Fume, and Mist Respirators for Permissibility, Schedule 21, United States Bureau of Mines.

will be restricted to members of medical societies that are component parts of the American Medical Association was approved.

The tentative program for the forthcoming annual congress was approved.

Resolved, That the problem of the recognition of specialists in fields related to internal medicine requires further study and that the Council is not prepared to take action at this time.

Resolved, That the Council will extend its approval to such special examining boards as may furnish satisfactory evidence of the reliability of their procedure in the examination and certification of candidates and who conform to the standards adopted by the House of Delegates.

Resolved, That the lists of pathologists and radiologists as submitted be approved.

Resolved, That the Council assist and encourage state medical societies in offering postgraduate courses of instruction by (a) a study of the methods proposed at the Nashville meeting of the Association of American Medical Colleges, (b) a discussion at the meeting of state secretaries and (c) presentation of papers at the next annual congress.

Resolved, That the acceptance of well qualified graduates of foreign medical schools by hospitals approved for internships should not jeopardize the standing of the hospitals with the Council, provided suitable graduates of American medical schools are given first opportunity.

Resolved, That the ophthalmic service in registered hospitals be under the direction of a qualified ophthalmologist and that assistants and technicians be under his supervision.

Resolved, That the lists of hospitals for approval or otherwise be acted on in accordance with the recommendations of the staff.

WILLIAM D. CUTTER, Secretary.

MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next two broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

November 22. Eat, Drink and Be Merry.
November 29. Holiday. No Broadcast.
December 6. Keep Fighting Diphtheria.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

November 20. The Doctor of Tomorrow, W. W. Bauer, M.D.
November 27. Dollars and Disease, Morris Fishbein, M.D.
December 4. The Quick Lunch, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Symposium on Heart Disease.—The heart committee of the San Francisco County Medical Society will hold its fifth graduate teaching course on heart disease, November 21-22. Sessions will be held at Mount Zion, San Francisco, University of California and Stanford University hospitals and the headquarters of the society. The final evening session will be in the nature of a clinical pathologic conference on heart disease, followed by a discussion of thyrotoxicosis in the treatment of congestive failure and angina pectoris.

Personal.—Dr. Miley B. Wesson, San Francisco, was awarded a silver medal by the Carnegie Hero Fund Commission, it was announced, October 27.—Dr. Albert J. Sipple has been appointed health officer of South Pasadena, succeeding Dr. Edward J. Johnston, and Dr. Gilbert B. Furness, health officer for Visalia, succeeding Dr. Addison W. Preston.

Graduate Medicine.—The University of California School of Medicine is conducting graduate instruction in Sacramento, Santa Rosa, Fresno, Eureka and San Jose, in response to the demand of physicians in the state for extramural teaching. Members of the medical faculty direct these sessions on alternate Fridays and Saturdays of each month during the teaching year.

DELAWARE

Health at Wilmington.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended November 3, indicate that the highest mortality rate (21.5) appears for Wilmington, and the rate for the group of cities as a whole, 10.6. The mortality rate for Wilmington for the corresponding period last year was 11.3 and for the group of cities, 11.1. The annual rate for eighty-six cities for the forty-four weeks of 1934 was 11.3 as against a rate of 10.8 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

DISTRICT OF COLUMBIA

Hospital Abandons Laboratory "Practice of Medicine."—The custom of charging private patients in its university hospital for "purely professional services" by the laboratory departments will be abandoned by George Washington University School of Medicine, in accordance with a resolution which the faculty adopted in October. This action was taken in order that such purely professional fees may be handled directly between the consultant and the patient. Professional services such as the interpretation of roentgenograms and supervision of administration of roentgen therapy are the responsibility of the consultant, the resolution further points out. On the other hand, the faculty regards the technical work of its laboratories as purely nonprofessional and approves in principle the levying of charges to any person or patient for technical services rendered and for the use of its laboratory facilities. Concluding the resolution, the faculty submits the thesis that the practice of medicine in public or private laboratories, staffed by non-professional people, begins only, if at all, at the point at which such technical data are interpreted and applied to the patient for the diagnosis, treatment and prognosis of disease processes.

FLORIDA

Dengue Fever.—According to newspaper reports, October 18, dengue fever was continuing in Tampa, between seventeen and twenty-four cases being reported daily. A campaign was initiated against the disease in Macon, Ga., October 17.

Personal.—Dr. and Mrs. George A. Davis, DeLand, observed their fiftieth wedding anniversary, October 22.—Dr. Harrison A. Walker, Miami Beach, was recently elected president of the Florida East Coast Medical Association, succeeding Dr. Leigh F. Robinson, Fort Lauderdale.

Society News.—At a meeting of the Dade County medical and dental societies, October 5, Dr. Frank R. Morrow and J. Harold Klock, D.D.S., Miami, discussed the relation of medicine to dentistry.—The first fall meeting of the Duval County Medical Society in Jacksonville, October 2, was devoted to a discussion of medical economics.—A symposium on carcinoma of the cervix and body of the uterus was a part of the program of the Pasco-Hernando-Citrus County Medical Society, recently. The society was entertained by Dr. George R. Creekmore, Brooksville. The speakers were Drs. William P. Adamson, Joshua C. Dickinson, Robert G. Nelson and William M. Rowlett, all of Tampa.

ILLINOIS

Southern Illinois Meeting.—At the sixtieth annual meeting of the Southern Illinois Medical Association in Mount Vernon, November 1-2, the following speakers were included on the program:

Dr. James J. Donahue, East St. Louis, Obstruction at the Pylorus.
Dr. Gershom J. Thompson, Rochester, Minn., Transurethral Prostatic Resection.
Dr. Percy H. Swahlen, St. Louis, Obstetrics.
Dr. Fred Z. Havens, Rochester, Minn., Malignancies About the Face.
Dr. Charles S. Skaggs, East St. Louis, What Is the Future of Medicine?
Dr. Frederick O. Fredrickson, Chicago, Analysis of Gastro-Intestinal Complaints with Reference to Diagnosis.
Dr. Harry Phillips, Anna, Modern Advances in Serology.
Dr. John B. Moore, Benton, Fractures.
Dr. Duncan D. Monroe, Edwardsville, The Home Treatment of Tuberculosis.
Dr. James S. Johnson, Cairo, Eye Injuries.

Society News.—The Christian County Medical Society was addressed in Taylorville, October 24, by Dr. Max S. Wien, Chicago, on "Relation of Dermatology to General Medicine."—At a meeting of the Will-Grundy County Medical Society, October 24, Dr. Edwin W. Hirsch, Chicago, discussed "Pathology, Diagnosis and Treatment of Prostatic Hypertrophy."—Speakers before the Pike County Medical Society in Barry,

October 25, were Drs. Edwin P. Sloan on thyroid deficiencies and Andrew J. Casner, types of pneumonia and their significance; both physicians are from Bloomington.—Members of the faculty of the University of Iowa College of Medicine, Iowa City, presented the program before the La Salle County Medical Society in Ottawa, October 18; Drs. Dean M. Lierle discussed the common cold and Nathaniel G. Alcock, diathermy in treatment of enlarged prostate.—Speakers before the Tri-County Medical Society (Warren, Knox, Henry) in Monmouth, October 18, were Drs. Julius H. Hess on "Present Status of Serum Therapy in Pediatrics"; William R. Cubbins, "Fractures Around the Knee Joint," and Frederick H. Falls, "Management of Eclamptogenic Toxemia." All are from Chicago.—The Kane County Medical Society adopted a resolution, October 11, declaring itself "opposed to the schemes grouped under the label of sickness insurance." Dr. Herman L. Kretschmer, Chicago, addressed the meeting on "Prostatic Obstructions."

Chicago

Personal.—A dinner was held in honor of Dr. Henry S. Houghton, director of clinics and associate dean of the Division of Biological Sciences, University of Chicago, November 5. Dr. Houghton recently resigned to become advisory representative of the China Medical Board of the Rockefeller Foundation. Speakers at the dinner included Frederic C. Woodward, LL.D., vice president of the university; Frank R. Lillie, dean, and Dr. Dallas B. Phemister, professor of surgery in the division.

Society News.—Speakers before the Chicago Gynecological Society, November 16, included Drs. Gustav Kolischer and Arthur H. Curtis on pathologic features of the female urethra and bladder, respectively.—Dr. Bernard H. Nichols, Cleveland, addressed the Chicago Roentgen Society, November 8, on "Value of Roentgenologic Examination in Right Abdominal Pain," and Dr. William E. Anspach, "Atelectasis, Bronchiectasis and the Triangular Shadow in Children."—At a meeting of the Chicago Pathological Society, November 12, speakers included Dr. H. Gideon Wells and Maud Slye on "Tumors of Islet Tissue with Hyperinsulinism in a Dog."—Dr. Carl E. Badgley, professor of surgery, University of Michigan Medical School, addressed the Chicago Orthopedic Club, November 16, on "The Value of the Thrust Graft in Atrophic and Sclerotic Nonunion." Dr. Maurice A. Bernstein also spoke on "Cysts of the Semilunar Cartilage." A dinner in honor of Dr. Badgley preceded the meeting.—Dr. Clifford G. Grulee will give a public lecture, November 22, one of a series sponsored by the Chicago Heart Association; his subject will be "The Spoiled Child in Heart Disease." Dr. Newell C. Gilbert opened the series, November 8, with a discussion of the principal causes of heart disease.

INDIANA

Hospital News.—The Smith-Esteb Memorial Tuberculosis Hospital was dedicated at Richmond, October 7. Speakers included Murray Auerbach, executive secretary of the state tuberculosis association. A gift of \$100,000 by Mrs. David Esteb was largely responsible for the hospital, it was stated.

Personal.—Dr. and Mrs. Charles Titus, Wilkinson, entertained the Hancock County Medical Society at dinner, October 4; the occasion was the couple's twentieth wedding anniversary. Speakers were Drs. Rollin H. Moser and Louis H. Segar, Indianapolis, on "Diagnostic Interpretation of Gastro-Intestinal Symptoms" and "Recent Advancement in Pediatrics," respectively.

IOWA

Personal.—Dr. Fred L. Wells, Des Moines, medical director of the Equitable Life Insurance Company of Iowa, was elected president of the Association of Life Insurance Medical Directors at its annual convention in New York, October 20.—Dr. Edward H. Files was elected secretary of the Cedar Rapids Symphony Orchestra recently.

Tilton Restrained from "Practicing."—A permanent injunction restraining Lester J. Tilton, Clinton, from practicing medicine has been obtained by the state, according to the Des Moines Tribune. It was stated that while he did not have a license to practice medicine he had worked up a large cancer cure business. Early this year Tilton was sentenced to jail for thirty days for nonpayment of a \$1,000 fine imposed in federal court for violation of the federal food and drugs act.

Public Health Meeting.—The Iowa Public Health Association held its ninth annual meeting in Des Moines, October 26. Speakers included Drs. Garner M. Byington, medical

director, W. K. Kellogg Foundation, Battle Creek, Mich.; Orianna McDaniel, Minneapolis, of the Minnesota State Department of Health, and Earle G. Brown, Topeka, executive secretary, Kansas State Board of Health. Their subjects were, respectively, "The Michigan Community Health Project as Sponsored by the W. K. Kellogg Foundation," "Observations on an Outbreak of Virulent Smallpox in the Middle West," and "Kansas Accident Facts." The evening meeting was a joint session with the Des Moines Academy of Medicine and the Polk County Medical Society, at which the guest speaker was Dr. Russell L. Cecil, New York, on "Influenza and the Common Cold."

MARYLAND

Personal.—Francis M. Root, Ph.D., associate professor of medical entomology, Johns Hopkins School of Hygiene and Public Health, died at the Johns Hopkins Hospital, Baltimore, October 21, at the age of 45. Dr. Root was well known for his work in identifying insects carrying malaria and yellow fever and had led many expeditions into the interior of South America and other tropical sections to study mosquitoes and to devise methods of combating these diseases at the source. He was managing editor of the *American Journal of Hygiene*. A graduate of Oberlin College, Dr. Root had received the degree of doctor of philosophy from Johns Hopkins University.

MINNESOTA

Sentenced for Practicing Without License.—James A. Enright, Minneapolis, pleaded guilty, August 30, to practicing healing without a basic science certificate and was sentenced to thirty days in the Minneapolis Workhouse and placed on probation for one year. Enright's claims that he was a doctor and a graduate of the University of California were found to be untrue. According to the state board of medical examiners, he has no medical education, but during a strike in Minneapolis he received money for treating and caring for injured truck drivers.

Dr. Webb Gives First Bell Lecture.—Dr. Gerald B. Webb, Colorado Springs, formerly president, National Tuberculosis Association, will deliver the first John W. Bell Lecture, December 3. This lectureship was recently established by the Hennepin County Tuberculosis Association in the Hennepin County Medical Society (THE JOURNAL, August 18, p. 496). Dr. Bell, who died in 1933, was a member of the House of Delegates of the American Medical Association. He also served as president of the state medical association, the Hennepin County Medical Society and the Minnesota Academy of Medicine, and was a member of the state senate from 1891 to 1895. He was emeritus professor of medicine and at one time professor of physical diagnosis and clinical medicine at the University of Minnesota Medical School. Dr. Webb is president of the Colorado State Board of Medical Examiners and past president of the state medical society.

MISSOURI

Tuberculosis Surveys.—The state tuberculosis association and the state department of health are cooperating in surveys throughout the state. Work in Morgan County, which included a tuberculosis and tuberculin testing study, has just been completed by the local tuberculosis association, and a similar survey is in progress in Johnson County. The Nodaway County medical and tuberculosis associations recently finished a survey of open cases. Plans are now being made to give the tuberculin test in contact cases.

Medical Section in Science Academy.—A medical section will be created at the meeting of the Missouri Academy of Science in Columbia, December 6. Dr. Dudley S. Conley, dean, University of Missouri School of Medicine, Columbia, is chairman of the new section. Charter members will be exempt from the entrance fee of \$1. Initial dues are \$1.50. Other sections to be formed at this meeting will be mathematics, physics, chemistry, astronomy, geology and geography, zoology, botany, anthropology, psychology, sociology, economics, history, philology, engineering, philosophy and political science.

Society News.—The St. Louis Neuropsychiatric Society will be addressed, November 26, by Dr. Louis L. Tureen on "Varicosities of the Vein of Galen."—Speakers before the St. Louis Medical Society, October 23, were Drs. Grayson L. Carroll on "Progress of Urology," and Waltman Walters, Rochester, Minn., on "Ureterosigmoidal Transplantations and Other Plastic Procedures for Congenital Abnormalities of the Genito-Urinary Tract." The program was given by the Southwestern Branch of the American Urological Association.—Dr. James H. Forsee, Denver, addressed the Boone County

Medical Society, October 2, on "Surgical Treatment of Pulmonary Tuberculosis."—Dr. J. Isfred Hofbauer, Cincinnati, addressed the Kansas City Obstetrical and Gynecological Society, September 27, on "Recent Views on the Etiology and Etiologic Treatment of the Late Toxemias of Pregnancy."—Dr. Dayton I. L. Seabaugh, Jackson, discussed the diagnosis and treatment of pneumonia before the Cape Girardeau County Medical Society, October 8.

NEBRASKA

Society News.—Dr. Ernest L. MacQuiddy, Omaha, addressed the Hall-Merrick-Howard Counties Medical Society, Grand Island, October 25, on "Allergic Problems in Everyday Practice."—At a meeting of the Third Councilor District Medical Society in Beatrice, October 16, speakers included Drs. William W. Waddell, Beatrice, on "Treatment of Pneumococcal Pneumonia"; John C. Thompson, Lincoln, "The Irritable Bowel and Its Treatment"; Melvin W. Binger, Rochester, Minn., "Hypertension," and Karl S. J. Hohlen, Lincoln, state medical relief administrator, "The Set-Up of the NERA with the Physician."—The Southwest Nebraska Medical Society held a meeting in McCook, November 12, with the following speakers: Drs. James E. M. Thomson, Lincoln, on "Fixed Traction with Kirschner Wire, Used in Treatment of Certain Fractures"; Carl R. Carlson, Wauneta, "Pertussis," and Carroll W. Dewey, Danbury, "Cyclic Vomiting in Children."

NEW YORK

Personal.—Dr. Herbert U. Williams, professor of pathology and bacteriology at the University of Buffalo School of Medicine, has retired after forty years of teaching. Dr. Kornel Ludwig Terplan, research professor of pathology since 1930, succeeded Dr. Williams.

Society News.—Drs. William F. Rienhoff Jr., Baltimore, and Edgar Mayer, Saranac Lake, addressed the Medical Society of the County of Nassau, October 30; on "Total Unilateral Pneumectomy" and "Treatment of Lobar Pneumonia by Artificial Pneumothorax," respectively.—A symposium on the eye was presented before the Buffalo Academy of Medicine, October 31, by Drs. Harry M. Weed, Ivan J. Koenig and Herbert H. Glosser.—Dr. George W. Crile, Cleveland, addressed the Medical Society of the County of Monroe, Rochester, November 1, on "Newer Methods of Treatment of Peptic Ulcer, Spastic Constipation and Indigestion."—Henry F. Vaughan, Dr.P.H., of Detroit, will address the Medical Society of Westchester County, White Plains, November 20, on "The Family Physician and Preventive Medicine."

New York City

The Brickner Lecture.—Dr. Moses Swick gave the fourth Walter M. Brickner Lecture at the Hospital for Joint Diseases, November 8. His subject was "Radiopaque Media in Urology."

Hospital News.—The program of the regular clinical society meeting at New York Polyclinic Medical School and Hospital included addresses by Drs. Damaso de Rivas, Philadelphia, on "Amebic Dysentery"; Francis G. Blake, New Haven, Conn., "Artificial Pneumothorax in the Treatment of Lobar Pneumonia," and Dr. Charles W. Stiles, Washington, D. C., "Medicozoological Aspects of the Race Problem."

Hospital Appointments Available.—The Hospital for Joint Diseases announces that an examination will be held December 26 at the hospital to fill six places on the general service, three to begin July 1, 1935, and three, Jan. 1, 1936, for two years' rotating service. The hospital provides maintenance and uniforms. Graduating students and graduates (unmarried men) of class A medical schools are eligible. Applications should be addressed to the director of the hospital, Madison Avenue and One Hundred and Twenty-Third Street.

NORTH CAROLINA

District Meetings.—At the annual meeting of the Seventh District Medical Society in Lincolnton, October 30, speakers included Drs. Paul R. MacFadyen, Concord, on "Idiopathic Epilepsy"; William G. Bandy, Lincolnton, "Coronary Thrombosis"; James M. Northington, Charlotte, "The Need for Vigorous Medical Leadership"; William M. Roberts, Gastonia, "Reconstruction of the Infantile Paralytic Cripple," and Addison G. Brenizer, Charlotte, "Ureteral Transplantations—Simplification of Methods." Dr. Paul P. McCain, Sanatorium, president of the Medical Society of the State of North Carolina, made an address at the banquet in the evening. Dr. Lester

A. Crowell Jr., Lincolnton, was elected president.—Drs. John Shelton Horsley, Richmond, Va., and Stewart R. Roberts, Atlanta, were guest speakers at the fall meeting of the Tenth District Medical Society, in Asheville, October 24. Dr. Horsley discussed "Symptoms, Diagnosis and Treatment of Cancer of the Colon and Rectum"; Dr. Roberts, "The Tachycardias and the Great Tachycardia." Dr. J. Rufus McCracken, Waynesville, was elected president.—Dr. Isaac H. Manning, Chapel Hill, was the guest speaker at the semiannual meeting of the Eighth District Medical Society at Elkin, October 16, on group hospitalization. Speakers on the scientific program included Drs. Kenneth B. Geddie, High Point, on "Prophylactic Immunization"; James H. McNeill, North Wilkesboro, "Artificial Fever Therapy," and Fred K. Garvey, Winston-Salem, "Tuberculosis of the Genito-Urinary Tract."

OHIO

Fifty Years of Service.—Dr. George D. Lummis, health commissioner of Middletown for forty-four years, was guest of honor at a banquet given by physicians of Middletown, October 24, celebrating his completion of fifty years as a physician. Dr. Bryan Sharkey was toastmaster and speakers included Mr. George M. Verity and Mr. B. F. Harwitz, Middletown; Dr. Ben R. McClellan, Xenia; Dr. Arthur O. Peters, Dayton; Dr. Mark Millikin, Hamilton; Dr. Elroy T. Storer, Middletown, and Dr. Lummis. Dr. Edward O. Bauer presented a watch to Dr. Lummis as a token of appreciation from his fellow physicians.

Memorial to Dr. Probst.—A memorial plaque honoring the late Dr. Charles O. Probst was dedicated at the Ohio State Sanatorium, Mount Vernon, October 27, the twenty-fifth anniversary of the founding of the hospital. Dr. Leslic L. Bigelow, Columbus, made the presentation speech and the plaque was accepted by John McSweeney, state director of public welfare. A scientific program of addresses on tuberculosis was presented by Drs. Henry Kennon Dunham, John H. Skavlem, Cecil W. Hickam and James N. Christensen, Cincinnati. Dr. Probst, who died in 1933, was for twenty-five years secretary of the state board of health, for ten years professor of hygiene, Starling Medical College, Columbus, and served as president of the Ohio Society for the Prevention of Tuberculosis and of the American Public Health Association.

OKLAHOMA

Clinical Conference in Oklahoma City.—The fifth annual conference of the Oklahoma City Clinical Society was held October 29-November 1 with headquarters at the Hotel Biltmore. About 600 physicians attended. Among guest speakers were:

Dr. Russell L. Cecil, New York, Modern Treatment of Lobar Pneumonia; Diagnosis and Treatment of Chronic Arthritis.
Dr. George Pinness, Los Angeles, Allergy as Diagnostic Problem in Respiratory Disease.
Dr. Temple S. Fay, Philadelphia, Treatment of Head Injuries.
Dr. Howard L. Beye, Iowa City, Intestinal Obstruction.
Dr. Walter L. Bierring, Des Moines, Iowa, President, American Medical Association, Acute Diseases of Blood-Forming Organs.
Dr. Otto H. Schwarz, St. Louis, Late Toxemia of Pregnancy.
Dr. Myrie G. Peterman, Milwaukee, Acute Infections in Infancy.

A public health meeting was held October 31, at which Dr. Bierring discussed history of medicine; Dr. Fay, headaches; Dr. Beye, pain in the abdomen; Dr. Peterman, children's crying; Dr. Albert Soiland, Los Angeles, cancer, and Dr. John J. Shea, Memphis, Tenn., care of children's eyes.

OREGON

Annual Registration Due December 1.—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to be registered annually on or before December 1, with the secretary of the board of medical examiners, and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days of default, and his failure to reregister within ninety days after December 1 is a misdemeanor.

PENNSYLVANIA

Personal.—Dr. Enoch H. Adams, Berwick, has been appointed surgeon in chief to the Center County Hospital, Bellefonte.—Dr. James Norman White, Scranton, has been named surgeon in chief to the Moses Taylor Hospital, Scranton.—Dr. Oscar Paul Holmer, assistant director of the state bureau of mental health, Harrisburg, has been named psychiatrist to the Berks County Mental Health Clinic, on a part time basis. He succeeds Dr. Ronald B. McIntosh, who resigned to become clinical director of Norristown State Hospital.—Dr. William Frederick Herbst has been chosen chief of the

medical department of Allentown Hospital to succeed the late Dr. Joseph M. Weaver.—Dr. Walter W. Hammond Jr., of the U. S. Public Health Service has been assigned as surgeon to the U. S. Northeastern Penitentiary at Lewisburg, replacing Dr. Russell Thomas, who has been transferred to Baltimore.

Philadelphia

Newbold Lecture.—Dr. Walter Bradford Cannon, Boston, delivered the thirty-third annual Mary Scott Newbold Lecture of the College of Physicians of Philadelphia, November 7, on "Stresses and Strains of Homeostasis."

Personal.—Dr. William Taylor, chief of staff of the Orthopedic Hospital, was the guest of honor at a reception given by the staff executives and the board of managers of the hospital, October 16, in appreciation of his fifty years of service to the hospital.

Portrait of Dr. Flick.—Friends of Dr. Lawrence F. Flick recently presented a portrait of him to Jefferson Medical College, from which he was graduated in 1879. Dr. Flick is still engaged in active practice. He is a former director of the Henry Phipps Institute and is the author of two books as well as of many articles on tuberculosis.

Hospital News.—Dr. Frank E. Leivy delivered the second of a series of nine health lectures for the public at Mount Sinai Hospital, October 24, on "Diet and Health"; Dr. Maxwell Scarf will deliver the next lecture, November 28, on arthritis and rheumatism, and Dr. Eugene Rush will speak, December 26, on "How to Keep Your Children Healthy."

Society News.—Dr. Austin T. Smith addressed the Philadelphia Laryngological Society, November 6, on "Bone Lesions of the Nose and Sinuses, with Special Reference to Hypertrophic Changes and Tumor Formation."—Dr. Herbert Lund, among other speakers, presented before the Pathological Society of Philadelphia, November 8, a paper on "The Incidence of Malignant Tumors at Philadelphia General Hospital, 1867-1934, with Special Reference to Primary Cancer of the Lung."—Speakers at a meeting of the Philadelphia Psychiatric Society, November 9, were F. Gilman Spencer, Esq., on "The Psychiatrist and the Law" and Raymond M. Remick, Esq., on "Wills and Testamentary Capacity."—Sir Harold Gillics, London, addressed the Philadelphia Academy of Surgery, November 5, on "Plastic Operations and Their Psychologic Effect," and Drs. John Stewart Rodman and William G. Leaman Jr., on "Surgical Risks, with Special Reference to the Cardiovascular System."

Pittsburgh

Society News.—Speakers before the Pittsburgh Academy of Medicine, October 23, were Drs. John D. Singley, on "Value of the Omentum in Abdominal Surgery, Particularly with Reference to Free Omental Grafts"; Henry C. Flood, "Congenital Defects," and Frederick B. Utley, "Treatment of Peptic Ulcer and Carcinoma of the Stomach."—The Allegheny County Medical Society has prepared a series of newspaper articles on diet and reducing, which are appearing in the Pittsburgh *Sun-Telegraph*.

WISCONSIN

Scarlet Fever in Milwaukee.—Scarlet fever cases in Milwaukee reached a high point of 961, October 29 newspapers reported. Dr. John P. Koehler, city health officer, asked the state board of health to reduce the quarantine period from four to three weeks in order to relieve crowded conditions at the South View Isolation Hospital, and the city common council appropriated \$10,000 as an emergency fund to help fight the epidemic. A campaign to locate carriers among school children was begun, October 16.

Society News.—Diagnosis and treatment of goiter were the subject of addresses at the annual meeting of the First Council District of the Medical Society of Wisconsin, Beaver Dam, October 10, by Drs. Marshall O. Boudry and David J. Twohig, Fond du Lac, and Arnold S. Jackson, Madison.—Drs. Alfred Blalock, Nashville, Tenn., and John P. Koehler, health commissioner of Milwaukee, were speakers before the Medical Society of Milwaukee County, October 12; their subjects were "Circulatory Changes in Shock" and "What Is Wrong with the Health Department?" respectively.—Dr. Emile F. Holman, San Francisco, addressed the Milwaukee Society of Clinical Surgery, October 13, on "Clinical and Experimental Observations on Pulmonary Suppuration."—Drs. Charles R. Marquardt and Herman A. Heise addressed the Milwaukee Academy of Medicine, September 18, on "Injection Treatment of Hydrocele" and "Alcohol in Relation to Automobile Accidents," respectively.—Dr. Ejvind P. K.

Fenger, Oak Terrace, Minn., addressed the Fond du Lac County Medical Society, Fond du Lac, October 16, on early diagnosis of tuberculosis.

GENERAL

Licenses Stolen.—Dr. David Hershkowitz, New York, reports that his diploma and two licenses issued by Maryland and Louisiana were stolen from his office during the week-end of October 20. A license and certificate of registration with the Los Angeles Health Department, together with a receipt for 1934 annual registration have been reported lost by Dr. Edgar Frank Mauer, Los Angeles.

Board of Psychiatry and Neurology Organized.—The American Board of Psychiatry and Neurology was organized at a meeting in New York, October 20, with the following officers: Drs. H. Douglas Singer, Chicago, president; Charles Macfie Campbell, Boston, vice president, and Walter Freeman, Washington, D. C., secretary. Other members are Drs. Lewis J. Pollock, Chicago; George W. Hall, Chicago; Franklin G. Ebaugh, Denver; Lloyd H. Ziegler, Albany, N. Y.; James Allen Jackson, Danville, Pa., and Adolf Meyer, Baltimore. A committee was appointed to consider plans for examinations, credentials and forms for application blanks. It is proposed to send application blanks to candidates soon after January 1935, and the first examination will probably be held in New York in June 1935. Further information may be obtained from the secretary, Dr. Freeman, 1726 Eye Street, Washington, D. C.

Society News.—The American Nurses' Association announces that recommendations for the Walter Burns Saunders Memorial Medal for distinguished service in nursing may come from persons other than nurses. Recommendations must be on file with the association, whose address is 50 West Fiftieth Street, New York, by December 31.—Dr. Ross V. Patterson, Philadelphia, was reelected president of the Association of American Medical Colleges at the annual meeting in Nashville, Tenn., October 29-31. Under a new plan, Dr. John H. Wyckoff, New York, was chosen president-elect. Other officers are: Drs. Thurman D. Kitchin, Wake Forest, N. C., vice president; Fred C. Zapffe, Chicago, secretary, and Basil C. H. Harvey, Chicago, treasurer; the next annual meeting will be held in Toronto, Oct. 28-30, 1935.—Dr. Leonce J. Kosminsky, Texarkana, was elected president of the Tri-State Medical Society (Arkansas, Louisiana, Texas), at its annual meeting, October 17, and Dr. George W. Parson, Texarkana, was named secretary. The next annual meeting will be held in Texarkana.

National Committee on Contraceptive Legislation.—The organization of a National Medical Committee on Federal and State Contraceptive Legislation has been announced. Its objective is the repeal of state and national laws restricting the freedom of the physician to prescribe contraceptive methods and devices, when it is his judgment that he deems it the proper treatment. Created by a local group of physicians in Washington, D. C., it bears no relationship to any medical society. It proposes to remain entirely independent of and unassociated with any lay groups advocating so-called birth control legislation and will not accept any financial aid from these sources. The committee has not yet selected a chairman, but other officers chosen are: vice chairman, Dr. Palmer Findley, Omaha; secretary-treasurer, Dr. Prentiss Willson, Washington, D. C. Dr. Everett D. Plass, Iowa City, was named chairman of the executive committee, Dr. Frederick C. Holden, New York, vice chairman, and Dr. Willson, secretary. Other members of the executive committee include the following physicians: Robert L. DeNormandie, Boston; James R. McCord, Atlanta; Fred J. Taussig, St. Louis; Owen Jones Toland, Philadelphia; George Gray Ward, New York; Frank W. Lynch, San Francisco; Henry C. Macatee, Washington; Adolf Meyer, Baltimore; Charles Jefferson Miller, New Orleans; Joseph C. Placak, Cleveland; William Allen Pusey, Chicago, and Frederick C. Warnshuis, San Francisco.

CORRECTION

Chiniofon Therapy in Amebiasis.—In his article in *THE JOURNAL*, October 20, page 1226, Dr. Alfred C. Reed stated that "Craig believes that chiniofon therapy requires bed rest, administration both by mouth and by rectum, and a careful diet." Dr. Reed desires to make clear that this statement refers to Dr. Craig's views as expressed in his article in *THE JOURNAL*, April 28, 1928. Dr. Craig's later views, expressed in an article in the *Southern Medical Journal* in December 1932, were that chiniofon is very effective without adjuvant treatment for carriers or those presenting slight symptoms of amebiasis.

The Protection of X-Ray and Radium Workers

With the object of preventing casualties to x-ray and radium workers, the British X-Ray and Radium Protection Committee was formed in 1921 as the result of cooperative action of the Royal Society of Medicine, the Roentgen Society, the British Association for the Advancement of Radiology and Physiotherapy (now the British Institute of Radiology incorporated with the Roentgen Society) the Institute of Physics, the Radium Institute and the National Physical Laboratory. The chairman of the committee is Sir Humphry Rolleston, and its members are leading radiologists and physicists. Its first recommendation was issued in 1921, and revised ones followed in 1923 and 1927. At the instance of the British committee, international recommendations for x-ray and radium protection were adopted at Stockholm in 1928 by the second International Congress of Radiology. These were largely based on the British proposals. The problem of the adequate protection of the x-ray worker has been substantially eased by the introduction of the self-protected tube and more recently by the "shock-proof" tube and equipment. The committee has now issued a fourth report, which follows in the main the form of the International Recommendations and contains a number of alterations and additions based on the experience of the committee and the National Physical Laboratory, in its inspection and testing work carried out in association with the committee.

The present report lays down that the dangers of overexposure to x-rays and radium can be avoided by provision of adequate protection and suitable working conditions. The effects to be guarded against are (1) injuries to the superficial tissues and (2) derangements of internal organs and blood changes. The evidence available at present suggests that under satisfactory working conditions a healthy person can tolerate exposure to x-rays to an extent of about 0.2 roentgen daily. On the basis of continuous irradiation during a working day of seven hours, this figure corresponds to a dosage of 10⁻⁶ roentgen per second. No similar tolerance dose is at present available for the gamma rays of radium.

WORKING HOURS AND OTHER CONDITIONS

The following are recommended for whole time x-ray and radium workers: 1. Not more than seven working hours a day. No other hospital service. 2. Not more than five working days a week, the off days to be spent outdoors as much as possible. 3. Not less than four holidays a year, preferably consecutive. 4. No one to be employed whose blood or general health is unsatisfactory. Before work or training is begun, the normal leukocyte level should be found by making three afternoon counts. If none of the total counts reach 6,000 and none of the lymphocytes 1,200 the applicant should not be accepted for service. Periodic total and differential counts should be made every six months in the case of the x-ray worker and every three months in the case of the radium worker; but the six months period may be considerably extended for x-ray workers in departments that otherwise comply with the recommendations. A decided and sustained drop in total or lymphocyte counts indicates cessation of work and treatment for an adequate period. On resumption of work the circumstances should be reviewed to prevent recurrence.

GENERAL X-RAY AND RADIUM RECOMMENDATIONS

1. X-ray and radium departments should not be below the ground floor, and damp rooms should be avoided. 2. All rooms

should be provided with good natural lighting and facilities for admitting fresh air and sunshine. 3. They should be provided with adequate exhaust ventilation. 4. They should preferably be decorated in light colors. 5. A working temperature of from 18 to 21 C. (64.4 to 69.8 F.) is desirable. 6. The rooms should be large enough for convenient lay out of equipment. A minimum of 25 square meters is recommended for x-ray rooms and 10 square meters for dark rooms. Ceilings should not be less than 3.5 meters high. 7. X-ray generating apparatus employing mechanical rectifiers should preferably be in a separate room from the tube.

X-RAY PROTECTIVE RECOMMENDATIONS

1. The operator should on no account expose himself to a direct beam of the rays. 2. He should place himself as far as practicable from the tube. 3. The tube should be self protected with material of adequate lead equivalent. 4. For diagnostic work with other than completely protected tubes, the operator should be protected from stray radiation by a screen of minimum lead equivalent of 1 mm. 5. Screening examinations should be conducted as rapidly as possible with minimum intensities and apertures. The material of the diaphragm should be equivalent to not less than 2 mm. of lead. To prevent lateral escape of direct radiation, the diaphragm should be fitted within a protective enclosure. Palpation with the hand should be reduced to a minimum. 6. If small, the fluorescent screen should be provided with a protective "surround" for protection in all positions. 7. Screening couches and stands should provide arrangements for protecting the operator against scattered radiations from the patient. 8. Protective gloves should be lined with material of a minimum value of $\frac{1}{8}$ mm. of lead and protective aprons of 0.5 mm. 9. A calibrated ionization dose meter for use during treatment is strongly recommended. 10. During treatment the operator should be outside the x-ray room, behind a protective wall of lead equivalent to not less than 2 mm. for a single tube excited by voltages up to 200 kilovolts and proportionately increased for higher voltages. 11. Inspection windows in screens and walls should be of protective value equal to that of the surrounding screen or wall. 12. There should be protection against omission of a metal filter in treatment.

RADIUM PROTECTION

Protection is required against the effect of beta rays on the hands and gamma rays on internal organs. 1. For protection of the hands, reliance should be placed in the first place on distance. The radium should be manipulated with long-handled forceps and carried from place to place in long-handled boxes lined with at least 1 cm. of lead. All manipulations should be as rapid as possible. 2. When not in use, radium should be stored in a safe as distant as possible from the personnel. The safe should be provided with separate drawers individually protected. The thickness of lead varies from 8.5 cm. for 0.2 Gm. of radium element to 17 cm. for 10 Gm. 3. A separate room with exhaust fan should be provided for the make up of screened tubes and applicators, and occupied only during such work. 4. For protection against gamma rays during handling, a screen of not less than 2.5 cm. of lead should be used, and proximity to the radium should occur only during the actual work and for as short a time as possible. 5. For measurement there should be a separate room. 6. Nurses should not remain in proximity to patients being treated with quantities of radium exceeding 0.5 Gm.

RADON

Protection against the beta and gamma rays has likewise to be provided. 1. The handling of radon should be, as far as possible, during its relatively inactive state. 2. The escape of radon should be guarded against and the room in which it is

prepared provided with an exhaust fan controlled from the outside. 3. When radon is likely to come in direct contact with the fingers, thin rubber gloves should be worn. Otherwise the protective measures for radium salts should be carried out. 4. The pumping room should preferably be in a separate building. The radium in solution should be heavily screened.

A Change in the Law Dangerous to the Medical Profession

A recent change in the law, which allows survival of an action for damages after death has caused some concern in the medical profession. Formerly the law was *actio personalis moritur cum persona*. If a man died as the result of injury due to negligence, his relatives could not continue any suit pending at the time of death or begin a suit. But in the middle of the last century an act was passed allowing those dependent on the deceased, such as his children, to bring an action if death was due to negligence. This right was not only limited to dependents but was restricted in other ways. The action must be brought within a year of death and the amount of compensation must have reference to the degree of dependence. The law has been altered. An action can now be brought for personal injury caused by negligence, notwithstanding the death of the victim, and whether the death was caused by the negligence complained of or not. Further, the action may be brought at any time within six years of the injury. The *British Medical Journal* considers that the change in the law is fraught with grave danger to the medical profession and instances the case in which a patient dies on the operating table. He may have submitted to the operation knowing that it was his only hope and be the last person in the world to charge the surgeon with negligence. Yet the surgeon is exposed for six years to the risk of an action at the suit of those who are interested in the estate of the deceased. They need not have been in any way related to him or dependent on him. Again, a patient who has submitted to treatment or to an operation may subsequently die from some supervening injury or disease. His physician remains for six years exposed to the risk of an action, although the patient had no intention of bringing one and had no ground of complaint. The new law does show consideration for those liable to be affected by it by restricting the amount of damages. However, these must not be exemplary and damages to the estate which are merely the result of the death must not be awarded. For example, if an annuitant were to die, the resulting loss to his estate must not be considered. But the great grievance of the medical and other professions remains—that actions pending at the time of the death may be continued not merely for the benefit of dependents but for the benefit of any one interested in the estate.

Clinical Research at Guy's Hospital

Guy's Hospital has accepted the invitation of the Medical Research Council to cooperate in the establishment of a new unit for scientific research in clinical medicine. The council will provide the salary of a whole time director and his assistants, with the cost of all apparatus and research material. The hospital will provide the laboratory accommodations and maintain beds at the disposal of the director of the unit, who will ex officio be a member of the visiting staff with a seat on the medical committee and on the committee of the medical school. Dr. Ronald T. Grant, heretofore working in the service of the council in the department of clinical research at University College Hospital, has been appointed director of the new unit. The invitation was issued to Guy's Hospital by the Medical Research Council in accordance with its general policy of improving the facilities available in this country for the scientific study of disease in man, by means of increasing the number of higher appointments for whole time workers.

The money required for the purpose was released when the senior post formerly maintained by them at University College Hospital, held by Sir Thomas Lewis, received permanent endowment from the Rockefeller Foundation.

The London Medical Schools

At a dinner of the Knights of the Round Table Club, held in honor of London University, Sir Ernest Graham-Little (dermatologist and member of parliament for the university) referred to the new buildings at Bloomsbury of the university as the most ambitious program since the time of Wren. There were twelve famous medical schools in London, constituting the faculty of medicine of the university. The fame of these schools was enhanced by the fact that the ancient universities of Oxford and Cambridge sent their medical students to them for their clinical education. The facilities for medical education in London were unequaled anywhere else in the world. Two relatively new additions indicated the uninterrupted progress of the university. The London School of Hygiene and Tropical Medicine, founded ten years ago as the result of a gift of nearly \$2,500,000 from the Rockefeller Trust, had already established itself as the premier school of tropical medicine in the world. The newly created postgraduate school at Hammersmith, which was the joint responsibility of the government, the university and the London County Council, filled the most conspicuous gap that existed in the opportunities which London offered.

Centenarians

The deaths of thirteen reputed centenarians were registered in Scotland in 1933, all being women. The registered age was verified in five cases and disproved in three, while in the remaining five no evidence was available either to support or to disprove the claim. Of those verified, two were aged 100, two 101 and one 103. The practice of endeavoring to verify the ages of reputed centenarians was begun in 1910. Since that date 331 such deaths have been registered, 51 of men and 180 of women. Of the 331, 171 were verified and 54 disproved, while for 106 no evidence was available.

The French Surgical Congress

The forty-third annual meeting of French surgeons has just been held in Paris. Every year, three subjects are chosen by the members of the congress to be discussed during the following year's session. Two members are designated to make a thorough survey of the literature of the subject assigned to them and to include any work that they may have contributed. The subjects chosen for this year were "Pathogenesis and Treatment of Proliferating and Stricture-Forming Proctitis," "Treatment of Suppurative Arthritis of the Knee (War Injuries Excepted)" and "Surgery of the Suprarenals." These papers are sent in book form to the members about a month before the congress, thus enabling them to be better prepared to take part in the discussions.

PATHOGENESIS AND TREATMENT OF PROLIFERATING AND STRICTURE-FORMING PROCTITIS

Gatellier of Paris and Weiss of Strasbourg reached the following conclusions on the first of these subjects: A proliferating and stricture-forming proctitis is only one of the clinical manifestations of a much more generalized condition, characterized essentially by a lymphangitis, which may have its origin simultaneously or individually (in only one location) in the lymph vessels of the perineal, anorectal or inguinal region, genitalia or iliac fossa. In the majority of cases, such a proctitis is due to the virus of the Nicolas-Favre disease. It is

proposed by the authors to abandon the term "benign lymphogranuloma" and to adopt the terms "disease of Nicolas-Favre, inguinal poradenitis or poradéno-lymphite inguino-ilio-périnéale" following the work of Frei and others during the last ten years on this so-called fourth venereal disease. One can exclude syphilis, gonorrhea and the mycoses as etiologic factors. Tuberculosis can be considered only as a rare cause. The review of 139 reports of operations for inflammatory strictures of the rectum demonstrates that surgical treatment is of no avail because recurrence is the rule, even when resection is performed at a level where the tissue appears normal. This failure is due to a proctitis, which is constantly advancing by way of the lymph vessels. This proctitis results in the formation of a diffuse fibrous induration progressively involving the perirectal, perineal, ischiorectal and subperitoneal tissues. The subjacent progressive lymphangitis is found even in apparently normal tissue.

Nonoperative measures and a colostomy, only when obstruction occurs, are recommended, instead of resection, until the time when some specific treatment for the virus of the Nicolas-Favre disease has been found.

TREATMENT OF SUPPURATIVE ARTHRITIS OF THE KNEE

Of the second subject chosen for discussion, Huet of Paris and de Fourmestraux of Chartres gave an equally thorough review. Every wound in the vicinity of the knee in civil practice should be explored and disinfected as a prophylactic measure. The cases in which acute suppuration is evident can be divided in adults into moderate and severe. In the former, one can try simple exploratory puncture. If the fever persists or the general condition of the patient indicates at the onset that puncture alone will not suffice, an arthrotomy followed by early mobilization in the strictly synovial forms yields the best results. To prevent the incision from closing, the synovial membrane should be sutured to the skin. Early mobilization can be made much less painful by the use of large injections of procaine hydrochloride into the lateral ligaments and into the insertions of the quadriceps. For the severe cases in adults, simple arthrotomy must yield to more radical methods. The authors warmly recommended the drainage operation employed in war injuries of the knee; i. e., removal of the patella, resection of the ends of the femur and tibia, and synovectomy. The same methods were recommended for children, with the exception that early mobilization could not be carried out so easily.

SURGERY OF THE SUPRARENALS

On the third subject the paper prepared by Leibovici (Paris) and Stricker (Mulhouse) constitutes a monograph, which will be a landmark in this rapidly developing field of surgery. The authors believe that one is justified in predicting some very gratifying results following operations for benign tumors of the medullary portion (hypertension syndrome) or of the cortical portion (genitosuprarenal syndrome).

Operative intervention for malignant tumors has not been successful. The technic is difficult, the immediate mortality high and recurrence frequent, taking place earlier in tumors of embryonal character. Malignant tumors are also commonly bilateral. Suprenalectomy is of no value in epilepsy. In certain cases of hypertension, especially those of paroxysmal type and those of the menopause, some brilliant results have been reported. But there have also been some failures in hypertension cases.

In thrombo-angiitis obliterans (Buerger's disease) of the extremities, suprenalectomy is indicated in cases in which the vessels are still permeable, capable of vasodilatation. Lumbar sympathectomy offers a better prognosis in these cases than suprenalectomy. Too few patients with Raynaud's disease have been operated on to enable one to draw any conclusions. Denervation of the suprarenals for hyperthyroidism

seems to have a favorable action in lowering the basal metabolism rate, especially for cases not benefited by repeated thyroidectomies.

OPERATIVE TREATMENT OF ACUTE PANCREATITIS

In their paper, Brocq and Varangot said that thus far surgery in acute pancreatitis has not been successful, because much remains obscure as to the initial causes. A rational treatment should be based on the prevention of the conditions that lead to activation of the pancreatic secretion, to check these causes when they have once begun and to combat the shock that results from them. Treatment varies according to whether one is dealing with the aseptic or the suppurative form. The former represents the real evolution of pancreatic autodigestion from the stage of activation of the trypsin within the gland itself. Death in aseptic pancreatitis seems to be due to toxemia similar to that observed in severely jaundiced patients. It would seem as though, as a result of hepatic insufficiency, certain incompletely metabolized proteins enter the circulation. The object of treatment should be to drain the pancreas, eliminate the cause of the pancreatitis, especially drainage of the biliary tract, combat the shock and intoxication and attempt to save as much as possible of the pancreas itself. The gallbladder should be drained and calculi removed, at the same time an examination of the stomach and duodenojejunal region being made if the patient's condition permits. If there is hypochloremia and hyperglycemia in addition to shock, the former should be treated by sodium chloride intravenously and the latter by insulin. In favorable cases one sees a decided improvement in from two to three weeks. Death often occurs two or three days after operation. The mortality of these aseptic cases remains between 30 and 50 per cent; perhaps with earlier operation and drainage of the biliary tract, it may be lowered.

As to the cases due to infection, a division into suppurative and gangrenous forms is very difficult. They develop rapidly in persons apparently in the best of health. One can observe the formation of a swelling in the epigastric region or palpate a deep-seated, diffuse, fixed, painful mass. At operation one finds an infected hematoma in which lie gangrenous shreds of pancreatic tissue. Unless operation is performed in these cases, death from sepsis or peritonitis occurs. In some cases the process may be walled off with recurrent febrile attacks. There is a type of suppurative pancreatitis in which the condition develops gradually, leading to the formation of an epigastric mass. The pus may burrow toward the diaphragm or appear in the lumbar region or evacuate into a hollow viscus. Early operation will avoid these complications. The prognosis is more favorable in suppurative than in acute or hemorrhagic pancreatitis.

If the gland has undergone complete destruction, the outlook is very serious. The more localized the process, the better the prognosis. The anterior mode of approach to the pancreas is the only one to be considered.

In the next paper on the surgical treatment of chronic pancreatitis, Berard and Mallet-Guy considered as amenable to operation only cases in which the inflammatory changes were primary in the pancreas. Their character, whether benign or malignant, is discernible only by the clinical behavior of the tumor; that is, if it diminishes in size, it is benign and vice versa. An eighteen months cure stamps the lesion as being of noncancerous nature. This is due to the fact, at least at the beginning of the disease, that the clinical picture of a cancer in a certain number of cases, and of a benign chronic pancreatitis, is identical. Even exploratory operation does not always enable one to make a differential diagnosis. The biliary origin of chronic pancreatitis is evident in more than half of the cases, but it is difficult to determine the route of infection. Icterus and pain are the most reliable symptoms. The jaundice is considered generally to be due to an obstruction of the

common duct; but there are cases in which one cannot find such an obstruction, and postoperative injection of iodized oil into the biliary tract also fails to reveal an obstruction. At present, the surgical treatment of chronic pancreatitis is empirical. The operation that yields the best results is drainage of the biliary tract, even when there is no demonstrable obstruction. Such a drainage can be external (cholecystostomy or choledochotomy) or internal (among the latter, anastomosis of the duodenum and common duct is not to be recommended, because of the danger of ascending infection of the bile ducts). The best results follow anastomosis of the gallbladder and stomach. External drainage operations are more likely to be successful if drainage of the gallbladder is combined with that of the hepatic duct. Chronic pancreatitis with icterus can be cured in 75 per cent of the cases, and in an even larger number if there have been no previous lesions of the gallbladder. Drainage of the common duct is even more efficacious than that of the gallbladder, but there is danger of a permanent fistula. In chronic pancreatitis without icterus, drainage of the biliary tract is of little benefit. Direct drainage of the pancreas is not to be recommended. Even if a biliary fistula develops in cases of chronic pancreatitis after drainage of the gallbladder, one can always resort to an anastomosis between the latter structure and the stomach. Even if there are evidences of duodenal compression, gastro-enterostomy is rarely indicated.

Abuse of War Pensions in France

That France also has its pension troubles is the subject of an article in a recent number of the *Siècle médical*. Jan. 1, 1933, there were about 1,181,000 persons drawing pensions. Of these, 60,143 receive an indemnity of 100 per cent and 278,000 one of 10 per cent. The total sum spent for pensions is about seven billion francs annually (nearly five hundred million dollars at the present rate of exchange). One billion francs (seventy million dollars) is spent for those having major war injuries and those who were gassed, and four billion francs (over 280 million dollars) for those who are ill or "feign illness." About one third of those who receive pensions were noncombatants, such as workers in munitions plants.

During the first years after the war, these "medical parasites," as the writer terms them, did not receive any pension at all. Following the passage of a law in 1919, pensions were allowed to every one, whether in active service or not, "on whom a disease was found, it being taken for granted that such condition had been contracted or had been made worse by the dangers, accidents or fatigues of service." Every one who had a certificate of some acute illness, no matter if only of short duration and mild in nature, issued during the war, now applies for a pension.

This situation has assumed such political importance that it will require a strong hand to control it.

MOSCOW

(From Our Regular Correspondent)

Oct. 6, 1934.

Reform of Medical Education in the Soviet Union

In May 1934 an all union conference on medical education was called at Moscow to discuss the project of reorganization of medical education. In the medical school a five year course will be organized. The first five semesters will follow a common program. In the fifth year the students are to study medicine in connection with their future specialty. In all medical schools there will be curative and prophylactic faculties, but the pediatric and hygienic courses will be given only in universities where there are enough qualified teachers. The obstetric faculty will be a part of the curative-prophylactic faculty. The faculty of physical culture will be closed, but the study of physical culture will be obligatory on every other

faculty. The preparation of physicians by means of correspondence courses is annulled. Many research institutes will be united with faculties of medicine in order to make the latter centers of scientific thought. The oldest medical institutes of Moscow, Leningrad, Tomsk, Kazan, Rostov on Don and Voronezh will be reorganized as medical schools. Government examinations will be established. Persons entering faculties of medicine will have to be much better prepared than previously. Many new textbooks will be written for students. In the autumn of 1934, 9,500 new students will be received in the faculties of medicine. The number of young men desiring to receive medical education is growing.

Academician I. P. Pavlov

September 27, the eighty-fifth birthday of the physiologist Ivan Petrovitch Pavlov was celebrated by the Soviet Union. Professor Pavlov was born in the family of a priest at Riazan and received his early education in a seminary. In 1870 he went to St. Petersburg, where he attended the faculty of natural sciences and began his study of physiology under the guidance of Professor Zion. His first work, on innervation of the pancreas, published in 1874, was awarded a gold medal. After graduating at the university, he entered the military medical academy, simultaneously working as assistant to Professor Zion. He went to Germany in 1877, where he studied physiology of the gastro-intestinal tract with Professor Heidenhain. Coming home he took up research on the physiology of the blood. In 1879 he graduated from the academy but remained there for further study. He directed for ten years the experimental laboratory of the clinic of the physician Prof. S. P. Botkin. In 1884-1886 Pavlov worked abroad with Ludwig and Heidenhain. He published several papers on the pancreatic juice after returning home. He received the degree of doctor of medicine in 1883, became a private dozent in 1884 and was professor of pharmacology at the military medical academy in 1890. He was appointed to the chair of physiology in 1896, which he occupied till 1924.

In 1897 Professor Pavlov summarized the results of his work in his classic monograph "Lectures on the Digestive Glands." He was awarded for these researches the Nobel prize in 1904. In 1906 he was elected a member of the Russian Academy of Science. Professor Pavlov is a member of numerous foreign academies and scientific institutions and he has received many international prizes for his scientific work.

In 1903 in the International Congress of Physiologists in Madrid he read his well known paper on the experimental psychology and psychopathology of animals, which became the basis of a new chapter in physiology. There are hundreds of scientific reports made under the guidance of Professor Pavlov on the question of conditional reflexes, which was first developed by him.

In his two books "Twenty Years' Experience in the Experimental Study of the Higher Nervous Reactions of Animals" and "Lectures on the Work of the Cerebral Hemispheres" he gave for the first time a complete systematic statement of the theory of conditioned reflexes.

The Soviet government has always been attentive to Pavlov. In the difficult year of 1920 there was published by Lenin a special decree about the edition of Pavlov's works, which provided good working conditions for the pursuit of his scientific studies. Five years ago the government published another decree about the organization of special laboratories in the village of Coltuschi (near Leningrad) with a special building for Pavlov's work. The Council of People's Commissars of the Soviet Union in recognition of his eighty-fifth anniversary established an annual prize of 20,000 rubles for the best work in physiology and five scholarships of 500 rubles monthly each for young scientists in the field of physiology. The govern-

ment will publish in 1935-1936 all of Pavlov's works and will assign for his biologic station in Coltuschi 1,000,000 roubles yearly. A street in Leningrad will bear Pavlov's name. Talking pictures devoted to Pavlov and his research are now being made under the guidance of the pupils of Pavlov—Professors Podcopajev, Féodorov and others. The first series of pictures will be ready for the opening of the fifteenth International Physiologic Congress in the Soviet Union in August 1935.

Besides his scientific study, Professor Pavlov works every day physically and enjoys sport. In the parks of Coltuschi he plays skittles and rides a bicycle. At present he directs three large laboratories. Nearly all chairs of physiology in the Soviet Union are occupied by his pupils, many of whom are known the world over—Professors Orbeli, Bicov, Féodorov, Speransky, Rozenkov, Savitch, Frolov, Zeleni and others.

The Fifth Congress of Physiologists

The fifth All-Union Congress of Physiologists, Biochemists and Pharmacologists was held at Moscow, June 25-30. Prof. I. P. Rosenkov was elected president of the congress. About 250 papers were read at the meetings. The sections of the congress were on (1) comparative physiology, (2) physiology of nourishment, (3) biochemistry, (4) physiology of work, (5) experimental physiology and (6) pharmacology and industrial toxicology. The meeting of June 26 was devoted to the question of neurohumoral regulation. Prof. Leo A. Orbeli of Leningrad and Prof. D. E. Alpern of Kharkov read papers. June 27, three papers were read. The first one was by Prof. A. N. Palladin, who spoke on the biochemistry of muscular activity. Investigations on the influence of athletic training on the content of lactic acid in muscles demonstrated that the training causes no accumulation of lactic acid. Professor Palladin spoke about the influence of fatigue on the oxidative processes that are not immediately connected with muscular work. Prof. I. S. Beritov of Tiflis spoke on the psychonervous elements of individual behavior of the higher vertebrates. He considers behavior the total reaction of the organism, a reaction formed of the adaptation of the animal to the external medium and adaptation of the medium to the requirements of the organism. Professor Beritov refers every act of behavior to the reflexes, though the laws of the science of behavior and the science of reflexes are different. He studied the behavior of dogs by the method of free movements. The behavior of the animals based on their individual experience he calls "individual behavior." Psychology and reflexology cannot completely explain the behavior of men and animals. Professor Beritov's paper called forth many objections, mostly from representatives of I. P. Pavlov's school.

June 29 the plenary meeting of the congress was devoted to the origin of excitation and fatigue. Prof. A. A. Uchomsky of Leningrad said that tissues and organs that do not get tired do not exist. The problem of fatigue is outgrowing physiology and is becoming a social problem of expedient organization of work. Prof. D. S. Vorontzov of Kazan spoke of the origin of excitement and demonstrated that it is closely connected with metabolism. The electrical reaction of nerve and muscle does not exceed five seconds. Prof. D. L. Rubinstein of Moscow said that the use of oscillations of low frequency currents of some hundred million oscillations in a second opens new ways of studying the activity of a living cell.

In the section of comparative physiology, Prof. S. M. Leites of Kharkov read a paper on the regulation of fat metabolism. Dr. N. F. Popov of Moscow spoke about the vegetative functions of dogs after exclusion of the central nervous system.

In the section of pharmacology, Prof. V. V. Savitch of Leningrad reported on the influence of soporifics on the intestinal secretions. Small doses of morphine depress the secretion, having no influence on the brain; barbital and paraldehyde stop

the secretion of the intestine. Those observations point out the rôle of the central nervous system on the secretion of the intestine.

Professors Honored

The All Russian Executive Committee has given the title "honorary workers of medicine" to the following well known Russian professors: Prof. Serge N. Davidenkov of Leningrad, who wrote about 140 papers in neuropathology, biology and genetics; Prof. Leo A. Orbeli, who occupies the chair of physiology in the Military Medical Academy and in the All-Union Institute of Experimental Medicine; the surgeon Professor Andreas; L. Polenov, who in 1926 established the first chair of neurologic surgery in the Soviet Union; Prof. Ludwig I. Svergeevsky, a specialist in ear and throat diseases and one of the best Soviet surgeons; Prof. Serge U. Spasocutczky and Prof. George N. Speransky, a pediatrician, one of the founders of the Institute for Studying Motherhood and Childhood.

RIO DE JANEIRO

(From Our Regular Correspondent)

Sept. 15, 1934.

Indications for Roentgen Therapy in Rhinolaryngology

In a communication to the Society of Medicine and Surgery of São Paulo, Dr. P. Mangabeira Albernaz states that the two most important indications of roentgen therapy in rhinolaryngology are the papillomas of the larynx and rebellious hemorrhages. The roentgen treatment of papillomas is relatively recent and the results are spectacular. The treatment is simple and without danger if the right technic is followed. The author reports the case of a child, aged 12, with aphonia due to a papilloma of the left vocal cord. A cure was obtained and has been maintained for more than two years with irradiations of the larynx. Roentgen therapy is the method of choice for the treatment of papillomas of the larynx. Not as well known as the former procedure is the effect of roentgen rays on hemorrhages resistant to all other therapeutic means. In these cases, in which even transfusion fails, irradiation (irradiation of the hypophysis, of the spleen, of the lumbar medulla, and of the region in which the hemorrhage takes place) stops the hemorrhage suddenly. The author states that the use of roentgen rays has not only been a therapeutic measure but also a prophylaxis, under which conditions the irradiation must be done fifteen hours before the intervention. He cites the case of a child, aged 6, having a hemorrhagic diathesis of nineteen days that was diagnosed as purpura haemorrhagica. Blood examination showed 1,900,000 red cells, 10,000 leukocytes, 35 per cent hemoglobin, absence of hematoblasts, increase in the bleeding time and normal coagulation time. The polymorphonuclears were 43.5 per cent and the lymphocytes 43.5 per cent. After various treatments, tamponing, emetine, transfusion and so on, the case was given up as lost. The author advised roentgen therapy. The child was cured and has remained so for three years.

Caseation of Nerves of Leprosy

Dr. Enrico Branco Ribeiro has recently presented a well documented work to the Society of Medicine and Surgery of São Paulo on the surgical aspects of caseation of nerves in leprosy. On the basis of ten cases the author points out that in leprosy neuritis the peripheral nerves increase in volume; generally this is due to a fibrosis, but rarely there is necrosis followed by caseous coagulation and later liquefaction, surrounded by granulomatous tissue with fibroblasts, collagenous fibrils, giantocytes, lymphocytes, plasmocytes, histiocytes and newly formed vessels, but as a rule, with absence of *Mycobacterium leprae*.

This focus of caseation, which is found preferably in the endoneurium, passes to the epineurium and from there pro-

gresses in the direction of the superficial tissues, reaching eventually the skin surface. The author says that this is a surgical condition. He divides the cases into three groups. The first group includes those in which the caseous tumor has already pierced the skin, leaving a retractile scar that adheres to the nerve trunk and to the skin. In these cases the author does a neurolysis and envelops the reconstructed nerve with a piece of peritoncum recently collected. The second group comprises cases in which the disorder has attacked a nerve trunk at one or various points with formation of tumors. In these cases he proceeds to the dissection and extirpation of the tumors, to the incision of the nerve and to extraction of the caseous matter found in the endoneurium. The third group is composed of cases in which the disorder has attacked secondary cutaneous nerves and in which surgery cannot be conservative, the tumors being excised through section of the nerve branch above and below the affected part.

Congress of Neurology, Psychiatry and Legal Medicine

At the fourth Brazilian Congress of Neurology, Psychiatry and Legal Medicine, July 18-24, not less than thirty-eight papers on neuropsychiatry and legal medicine were presented and discussed. These contributions put up in a volume will give proof of the activity of the disciples of Juliano Moreira, Franco da Rocha, A. Austregésilo and Henrique Róxo, who have done so much to exalt the level of national medical culture.

Personals

Drs. Antonio Fontes and Valois Souto have been named by the government as representatives of Brazil at the tuberculosis conference in Warsaw.

JAPAN

(From Our Regular Correspondent)

Sept. 29, 1934.

The Abolition of Titles and Degrees in Advertisements

The Medical Association of the Western Provinces recently passed a resolution in its annual meeting to propose to the government the abolition of medical titles and degrees in advertisements or signs of any kind, for the following reasons: First, the present medical law prohibits the use of any kind of doctors' degrees in their advertisements. Second, generally speaking, the titles and degrees are conferred for theses on fundamental research and not for clinical work. The bearers are apt to use them in advertising their clinical skill. Third, there are too many who abuse their degrees, such as lending them to others or in advertising "patent medicine" and quack treatments. The new minister of education, considering it to be his great mission to reform the whole educational system, has put his hand to this work of reformation. He has taken up the question of titles and degrees, together with the question of shortening the number of school years as a whole. It is expected that a bill embodying the proposed reforms will be presented during the coming winter session of the diet. The government, it is believed, will support the bill, as there are many communities that support it.

The Regulation of Quackery

The rapid increase of medical impostors using various kinds of instruments, which they call their own invention, has forced the home office to issue new general regulations. An official committee was organized for this purpose, and at its first meeting the metropolitan police board issued the following reports: There were in Tokyo in August 4,473 lay practitioners. Almost half of them engage in what they call "electrohealing." Official control over them has not been strict because the methods ten years ago were quite simple and not believed to be harmful.

It was not, therefore, regarded as a violation of the medical act. But in 1929 the government declared some of them to be a kind of medical practice and forbade charlatans to use ultra-violet rays, high frequency current and the roentgen rays. In proportion to the increase in quacks, the manufacture of lamps and electrotherapeutic instruments increased, and many invalids were taken advantage of. The national health has come to be threatened by these harmful devices. A surprising fact is that there came to be a school of what is called electrohealing. It is not a school in its true sense, yet dares to assume this title. A flourishing school of this kind is said to have sent out more than 2,000 persons, who finished their course all over the country within a few years. The intelligent unemployed, who are everywhere at present, are ready to enter such a school. The course is usually six months, or a year and a half at the longest. After the students have paid a large school fee and bought an instrument of the school's own design at a high price, the queer title of "master of electrohealing" is conferred and they start their practice. Healers who use various rays are next in number. Palm therapy flourished widely a few years ago, but at its zenith a famous peer fell a victim of it. This caused a great sensation and led to this therapy being prohibited on sick people, and now it is allowed only to promote health and not healing. The new regulations are expected to cut the number of lay practitioners to two thirds when it is enforced.

Microbiologic Research Institute

The official gazette of September 17 says that a new microbiologic research institute has been established in connection with the Osaka Imperial University. There has been only one institute in Japan of this kind, the Infectious Disease Research Institute in Tokyo, which is chiefly devoted to studies of microbiology and to the manufacturing of preventive vaccines. Osaka is often called the gateway of infectious diseases from abroad, and so it will be more convenient for this kind of work than Tokyo. The new institute will study chiefly leprosy, tuberculosis, bacteriology and the prevention of epidemics. It will deal with infectious diseases that are closely connected with the surgical, internal and dermatologic departments. The first chief is Prof. Dr. Yashiro Furutake of the medical department of the university. Drs. Taniguchi, Satani, Imamura, Hosokawa and Sakurai, who are professors and assistant professors of the university, are on the staff. It will be completed in 1939 and the annual expenditure is expected to amount to over 330,000 yen. A large building will have been built by that time.

Kitazato Memorial Library

It is three years since the late Baron Dr. Shibasaburo Kitazato passed away. In order to commemorate his achievements and services in the progress of medical science, a plan for establishing a medical library has been made public by his friends. This will be the first library of medicine in this country. The sum of 300,000 yen will be contributed for the expenses of construction by the people at large. The chief of the committee is Baron T. Yamamoto, ex-minister of home affairs.

A New Medical College

It has been officially announced that a new medical college will be attached to the Formosa Imperial University at Taiwan and will open in 1936. Construction will be begun next year. Prof. Dr. S. Mita of the Tokyo Imperial University, a member of the organizing committee, will be appointed director, and twenty-four professors will be selected from various places by 1940, when the work will be completed. The present medical school in Formosa will be raised to the status of a university college of medicine. This will be the second medical college in Japanese territory.

Marriages

NORMAN BERNARD MURPHY, Augusta, Maine, to Miss Harriet Madeline Colgan of Mattapan, Mass., in September.

THOMAS BLACKBURN PAYNE, Fredericksburg, Va., to Miss Virginia Garnett at Gwynedd, Pa., October 20.

HARCOURT ALEXANDER MORGAN JR., Knoxville, Tenn., to Miss Sara Stone of Union City, August 9.

PIERRE G. JENKINS to Miss Emily Sinkler Martin, both of Charleston, S. C., at Florence, October 15.

JEFFERSON ALBRIGHT JONES, Philadelphia, to Miss Mildred Wolfe at Valley Forge, Pa., September 29.

PHILLIP P. PEASE, Chardon, Ohio, to Miss Marion Johnson of Middlefield, at Erie, Pa., October 5.

EDMUND LUDLOW KEENEY to Miss Eleanor Seymour Zimmerman, both of Baltimore, October 27.

GEORGE KENDAL DAZLY, Santa Monica, Calif., to Miss Doris Schwuchow of Los Angeles, October 11.

JAMES MITCHELL PARKER, Boston, to Miss Elizabeth Harding of Chestnut Hill, Mass., September 21.

MAYNARD F. POLAND, Indianapolis, to Miss Elwanda Phillips of Dunkirk, Ind., October 7.

OLIVER JOSEPH MENARD, Springfield, Mass., to Miss Janet T. Moran of Boston, November 7.

LORAIN WILLIAM WARD, Fairbank, Iowa, to Miss Graec Edwards of Blairstown, recently.

FRANK S. PECKOSH, Oxford Junction, Iowa, to Miss Collette Hart of Lost Nation, recently.

DOMINIC ZITO, Flushing, N. Y., to Miss Margery Armitage of New York, September 22.

HOWARD C. SPARKS, Monroeville, Ohio, to Miss Mary Shondel of Ottawa, recently.

ARTHUR CUNO FRANK ZODEL to Miss Beatrice Wilson, both of Johnstown, Pa., June 7.

GEORGE E. STAFFORD, Salina, Kan., to Miss Mary Greenwald at Falls City, Neb., July 5.

FRANCIS I. TAYLOR, Altoona, Pa., to Miss Elizabeth Hepler of Meadville, May 22.

ARTHUR E. PERLEY, Quincy, Ill., to Miss Ruth Buss in September.

Deaths

Lewis Linn McArthur @ Chicago; Rush Medical College, Chicago, 1880; member of the Colorado State Medical Society and the Society of Clinical Surgery; member and past president of the American Surgical Association; member and formerly chairman of the American section, International Surgical Congress; past president of the Chicago Medical Society; fellow of the American College of Surgeons; since 1886 chief surgeon to St. Luke's Hospital and consulting surgeon to the Michael Reese Hospital; consulting surgeon to the Grant and Evanston (Ill.) hospitals; was commissioned a major in the Medical Reserve Corps in 1917 and director of Base Hospital, number 14; Chevalier of the Order of Leopold of Belgium; aged 76; died suddenly, November 5, of heart disease.

Eugene R. Carpenter, Dallas, Texas; Jefferson Medical College of Philadelphia, 1898; member of the State Medical Association of Texas; past president of the El Paso County Medical Society; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the visiting staffs of the Baylor, Methodist and Parkland hospitals; retired with the rank of captain in the U. S. Army; aged 61; died, October 9, in a local hospital.

Fulton Schuyler Vrooman, London, Ont., Canada; University of Toronto Faculty of Medicine, 1904; member of the American Psychiatric Association; associate professor of psychiatry, University of Western Ontario Medical School; served with the Canadian Army Medical Corps during the World War; superintendent of the Ontario Hospital; aged 52; died, July 10, in the Victoria Hospital, following an operation for appendicitis.

Howard Perry Bellows, Boston; Boston University School of Medicine, 1877; professor emeritus of otology, professor of physiology, 1877-1885, and professor of otology, 1886-1929, at

his alma mater; fellow of the American College of Surgeons; consulting aurist to the Massachusetts Memorial Hospitals and Westboro (Mass.) State Hospital; aged 82; died, October 16, at his home in Cambridge.

William H. Van Gieson, Bloomfield, N. J.; College of Physicians and Surgeons, Baltimore, 1886; vice president and for seventeen years member of the board of education; aged 69; for many years on the staff of the Mountinside Hospital, where he died, September 7, of injuries received when he fell over a rock, while at his summer home in Boothbay Harbor, Maine.

John Randolph Garrett @ Roanoke, Va.; University College of Medicine, Richmond, 1898; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staff of the Roanoke Hospital; aged 65; died, August 28, in the Jefferson Hospital, of uremia and hypertrophy of the prostate.

Jacob Lincoln Schoch, New Ulm, Minn.; University of Michigan Medical School, Ann Arbor, 1885; an Affiliate Fellow of the American Medical Association; member of the state board of medical examiners, 1891-1896; aged 71; on the staff of the Loretto Hospital, where he died, September 22, of pulmonary thrombosis and pleurisy.

Thomas Kelly Van Zandt, Louisville, Ky.; Kentucky University Medical Department, Louisville, 1902; at one time adjunct professor of obstetrics, University of Louisville School of Medicine; on the staffs of the Norton Memorial Infirmary and St. Anthony's Hospital; aged 59; died, September 16, of cerebral hemorrhage.

Edward Andrew Tracy, Keene, N. H.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1902; member of the New Hampshire Medical Society; served during the World War; aged 57; on the staff of the Ellicott Community Hospital, where he died, September 2, of peritonitis, following an operation.

Alfred Forbes Blackhall, Schenectady, N. Y.; University of Vermont College of Medicine, Burlington, 1918; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; on the staff of the Ellis Hospital; aged 39; died, October 24, of embolus following multiple fractures.

Leonard Ernest Neale, Baltimore; University of Maryland School of Medicine, Baltimore, 1881; professor emeritus of obstetrics at his alma mater; member of the Medical and Chirurgical Faculty of Maryland; fellow of the American College of Surgeons; aged 75; died, October 19, of heart disease.

John Alexander MacArthur, Winnipeg, Manit., Canada; McGill University Faculty of Medicine, Montreal, Que., 1885; professor of diseases of children, University of Manitoba Faculty of Medicine; on the staffs of the Winnipeg General Hospital and St. Boniface Hospital; aged 86; died, August 26.

Charles Wardsworth Wright, Longmeadow, Mass.; University of the City of New York Medical Department, 1888; member of the Massachusetts Medical Society; served during the World War; on the staff of the North Adams (Mass.) Hospital; aged 70; died, September 25, of uremia.

Frank A. Metcalfe, Chicago; Hahnemann Medical College and Hospital, Chicago, 1897; formerly professor of materia medica and internal medicine at his alma mater; on the staff of the Jackson Park Hospital; aged 61; died, October 20, of essential hypertension and cerebral thrombosis.

Harry Parker Thompson, Brookville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1890; member of the Medical Society of the State of Pennsylvania; on the staff of the Brookville Hospital; aged 72; died, September 23, in the Cleveland (Ohio) Clinic Hospital, of hepatitis.

Samuel C. Broadstreet @ Mount Pleasant, Texas; University of Louisville (Ky.) School of Medicine, 1888; past president and secretary of the Titus County Medical Society; aged 70; died, October 12, in the Paris (Texas) Sanitarium, of disease of the prostate and pyelonephritis.

Frederick Augustine Rupp, Lewistown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1900; member of the Medical Society of the State of Pennsylvania; formerly member of the board of health of Lewistown; served during the World War; aged 58; died, July 23.

John Allen Thames, Jackson, La.; Tulane University of Louisiana Medical Department, New Orleans, 1908; member of the Louisiana State Medical Society; superintendent of the East Louisiana State Hospital; aged 52; died suddenly, September 30, at Harvey, of heart disease.

John Albert Boger @ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1889; fellow of the

American College of Surgeons; for many years police surgeon; on the staffs of the Episcopal, Stetson and St. Mary's hospitals; aged 65; died, October 20.

Christopher Hamilton Tebault Jr., New Orleans; Tulane University of Louisiana Medical Department, New Orleans, 1895; member of the Louisiana State Medical Society; veteran of the Spanish-American War; aged 66; died, September 4, of carcinoma of sigmoid and rectum.

David Thomas Tayloe Jr. • Washington, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1919; fellow of the American College of Surgeons; aged 40; connected with a hospital bearing his name, where he died, September 14, of edema of the brain.

Eugene L. Evins, Wilburton, Okla.; Tulane University of Louisiana Medical Department, New Orleans, 1892; member of the Oklahoma State Medical Association; aged 69; died, August 31, in St. Mary's Infirmary, McAlester, of acute emphysema of the gallbladder.

Charles M. Braidwood, Imlay City, Mich.; Detroit College of Medicine, 1900; member of the Michigan State Medical Society; past president and secretary of the Lapeer County Medical Society; aged 59; died in October at Port Huron, of valvular heart disease.

John Albert Williams • Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; aged 67; on the staff of the Ohio Valley General Hospital, McKees Rocks, where he died, September 20, of diabetes mellitus and tuberculosis of the lungs.

Harmon Silas Trueman, Medford, Mass.; University of Pennsylvania School of Medicine, Philadelphia, 1880; member of the Massachusetts Medical Society; aged 76; died, September 1, in the Trull Hospital, Biddeford, Maine, of coronary occlusion.

William Smith O'Brien, Chicopee, Mass.; Tufts College Medical School, Boston, 1905; formerly member of the board of health and school committee; on the staff of the Mercy Hospital, Springfield; aged 53; died, September 3, of heart disease.

William F. Farley • Holden, W. Va.; University of Louisville (Ky.) School of Medicine, 1893; past president of the Logan County Medical Society; medical superintendent of the Holden Hospital; aged 68; died, September 26, of myasthenia gravis.

Leander D. Keith, Anna, Ill.; Hospital College of Medicine, Louisville, Ky., 1896; member of the Illinois State Medical Society; aged 69; died in October as the result of a fall from a third story window of the Missouri Baptist Hospital, St. Louis.

William Minor Bryan • Senior Surgeon, U. S. Public Health Service, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1906; aged 52; died, October 5, of angina pectoris and coronary sclerosis.

Edward L. C. Richter, St. Louis; Beaumont Hospital Medical College, St. Louis, 1897; member of the Missouri State Medical Association; formerly coroner and alderman; aged 66; died, September 6, of cerebral hemorrhage.

Starr Clarence Hollis • Adams, N. Y.; Syracuse University College of Medicine, 1900; health officer for thirty-four years; served during the World War; aged 56; died suddenly, September 10, of coronary occlusion.

Willis Rollin Congdon, Santa Cruz, Calif.; Rush Medical College, Chicago, 1889; member of the California Medical Association; aged 66; died, August 18, of bronchopneumonia, chronic pyelitis and chronic myocarditis.

Edwin James Glass Valentine, Jersey City, N. J.; New York Homeopathic Medical College and Hospital, 1894; formerly member of the county board of health; aged 64; died, August 27, of aplastic anemia.

John Preston Ferguson, Louisville, Ky.; Jefferson Medical College of Philadelphia, 1892; member of the Kentucky State Medical Association; aged 68; died, October 8, of cerebral hemorrhage.

Frank C. Robinson, Little Rock, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1896; member of the Arkansas Medical Society; aged 71; died, September 19.

John Angelo Lester, Nashville, Tenn.; Meharry Medical College, Nashville, 1895; emeritus professor of physiology at his alma mater; aged 69; died, September 27, of carcinoma of the prostate.

Lewis E. Robinson, Magee, Miss.; Memphis (Tenn.) Hospital Medical College, 1899; member of the Mississippi State

Medical Association; aged 64; died suddenly, October 2, of heart block.

Harry Willrich Oyer, Pittsburgh; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; died, August 2, in Toronto, Ont., Canada.

Silas Woodson Nossaman, Cunningham, Kan.; University Medical College of Kansas City, 1902; aged 60; died, September 15, in the Wesley Hospital, Wichita, of appendicitis.

Ralph L. Hoyt, Christiana, Pa.; Baltimore Medical College, 1898; member of the Medical and Chirurgical Faculty of Maryland; aged 58; died, October 2, of heart disease.

Samuel Yoffe, Chicago; Chicago College of Medicine and Surgery, 1916; aged 44; died, October 19, in the University of Pennsylvania Hospital, Philadelphia, of pneumonia.

Thomas Mason Staley • Bicknell, Ind.; Baltimore Medical College, 1903; served during the World War; aged 55; died, September 28, of chronic valvular heart disease.

Robert Alexander Twitchell, East St. Louis, Ill.; American Medical College, St. Louis, 1890; member of the Illinois State Medical Society; aged 77; died, September 21.

Jean Baptiste Delisle, Ottawa, Ont., Canada; Laval University Faculty of Medicine, Quebec, 1892; aged 72; died, August 11, in the Notre Dame Hospital, Montreal.

Warren Smith, Holland, Mo.; St. Louis College of Physicians and Surgeons, 1898; aged 62; was instantly killed, October 8, when he was struck by an automobile.

Robert McAdam, Hot Springs National Park, Ark.; Hahnemann Medical College and Hospital, Chicago, 1885; aged 85; died, July 24, of chronic nephritis.

Frank Thomas Roach, Newport, Mich.; University of Michigan Medical School, Ann Arbor, 1903; aged 56; died, October 17, of carcinoma of the stomach.

Charles Henry Gibbs, Ellsworth, Maine; Medical School of Maine, Portland, 1881; member of the Maine Medical Association; aged 83; died, August 27.

William Rockwell, River Hebert, N. S., Canada; Jefferson Medical College of Philadelphia, 1886; aged 75; died, September 28, of coronary thrombosis.

Uriah H. Farr, Paragon, Ind.; Indiana Medical College, Indianapolis, 1877; Civil War veteran; aged 87; died, October 2, of cardiorenal disease.

Jesse Mead Titterington, Marionville, Mo.; Nashville (Tenn.) Medical College, 1878; aged 79; died, September 15, of valvular insufficiency.

Zebulin Monroe Hampton, Centralia, Mo.; Marion-Sims College of Medicine, St. Louis, 1891; aged 77; died, October 3, of cerebral thrombosis.

Francis M. Siner, Terre Haute, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1884; aged 72; died, October 5, of uremia.

Aubrey Taylor Fuller, Vancouver, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1901; aged 59; died, July 15.

George B. Borgelt • St. Louis; Missouri Medical College, St. Louis, 1890; aged 70; died, October 21, of carcinoma of the liver.

John Thomas Vick, Wichita Falls, Texas; Gate City Medical College, Dallas, 1903; aged 72; died suddenly, September 17.

Preston Work Foote, Rosenberg, Texas; Hospital College of Medicine, Louisville, Ky., 1880; aged 75; died recently of uremia.

Homer John Tillotson, Los Angeles; College of Physicians and Surgeons, Baltimore, 1880; aged 77; died, September 3.

James Henry Anderson, Union City, Mich.; University of Michigan Medical School, Ann Arbor, 1888; died, September 1.

Frank G. Jackson • Muncie, Ind.; Louisville (Ky.) Medical College, 1894; aged 75; died, October 5, of heart disease.

Jerome Butz Weida, Philadelphia; University of Vermont College of Medicine, Burlington, 1883; died, August 29.

Alba Lee Smith, Detroit; Detroit College of Medicine, 1912; aged 44; died, September 30, of biliary cirrhosis.

Moses Hawkins Topping, Los Angeles; Louisville (Ky.) Medical College, 1896; aged 59; died, September 19.

Ernest C. Blanck, Park Ridge, Ill.; Jenner Medical College, Chicago, 1907; aged 72; died, October 10.

Correspondence

NEED OF DERMATOLOGISTS FOR DEEPER KNOWLEDGE OF ALLERGY

To the Editor:—In THE JOURNAL, October 27, page 1275, Dr. Coca begins his paper with the statement “If one should inquire which of the existing medical specialties would profit especially through a deeper knowledge of allergic disease, one would necessarily think first of dermatology.”

On page 1277 Dr. Coca says: “I have treated three patients according to Sulzberger’s plan, all of which were much more sensitive by skin test to oidiomycin than to trichophytin. One of the three, a traveling salesman with large lesions on both forearms and elsewhere on the body, was unable to take the injections regularly and during the few months of his treatment his skin sensitivity remained stationary and his local condition remained unchanged. This case was later seen to be one of psoriasis.”

The last sentence would seem to indicate that the need of the dermatologist for a deeper knowledge of allergy is equaled only by the need of the allergist for a deeper knowledge of dermatology.

JAMES H. MITCHELL, M.D., Chicago.

TANNIC ACID TREATMENT OF BURNS

To the Editor:—The other day, while leafing through the July issue of the *Country Gentleman*, I noted an article by Paul De Kruif expounding, in extravagant language, the discovery, by Davidson of the Henry Ford Hospital staff, of the efficacy of 5 per cent tannic acid lotions in cases of extensive burns. May I, apropos of this, quote the following paragraph from the *Pittsburgh Medical Review* of May 1890, page 170:

TANNIN IN THE TREATMENT OF BURNS

A correspondent of the *Pharmaceutische Zeitung*, speaking from his own experience, says that tannin cannot be too highly recommended as an application to burns, especially when very extensive, the skin being entirely removed. A 5 per cent solution is squeezed from a sponge over the denuded surface, which is then dressed with soft ointment, either with or without tannin. Pain immediately abates, and the healing process is wonderfully rapid. The tannin solution must, of course, be freshly applied as often as the dressing is renewed.—(Dixie Doctor.)

J. A. HAGEMANN, M.D., Pittsburgh.

THE PARENTERAL ADMINISTRATION OF CEVITAMIC ACID (ASCORBIC ACID) SOLUTIONS

To the Editor:—The ready availability of cevitic acid (ascorbic acid) in pure crystalline form has naturally suggested its parenteral administration in solution in acute scorbutic conditions (Schultzer, Paul: *Lancet* 2:589 [Sept. 9] 1933. Bauke, E. E.: *München. med. Wchschr.* 81:1240 [Aug. 10] 1934). In order to prevent untoward local reactions from such administration, which may be attributed to the drug, certain pertinent factors should be called to the attention of physicians.

Cevitic acid is a relatively strong acid and on dissolving in water yields a solution of low p_H value (about 3.4). Its acid solution injected intravenously would be partially neutralized by the buffer alkalis of the blood, but on subcutaneous, intramuscular or intradermal injection such neutralization might not be quick enough to prevent the sclerosing effect of a strong acid solution. We have observed skin sloughs in mice, rats, guinea-pigs and rabbits, within three hours after subcutaneous injection of 0.5 cc. of 5 per cent solution of cevitic acid, and after intradermal injection of 0.05 cc. of 2 per cent solution. No local reactions occur if the cevitic acid solution is neutralized with sodium bicarbonate just before such administration.

It is recommended that, if cevitic acid is to be administered parenterally, it be dissolved in sterile water and neutralized with one-half its quantity of sodium bicarbonate (yielding a solution about p_H 7.0) immediately before injection so that untoward local reactions may be avoided. The dissolving and neutralizing should be done just before administering, as otherwise there may be loss of effectiveness.

OBSTETRICS IN RURAL PRACTICE

To the Editor:—In view of the considerable discussion concerning the care of obstetric patients I desire to present, for your criticism, the following case. In particular, I desire your opinion concerning the conservative attitude during the first and second stages, and the manner in which the third stage was handled. Obstetric textbooks are not clear on the matter of how long a retained placenta may be left alone, but I have heard an outstanding obstetrician say that forty-eight hours would be a safe limit. Of course, spending eighteen hours at the bedside of a woman in labor is most inconvenient—and economically a loss—to the physician, but, to my mind, it is about the only safe way, at least in country practice. All too frequently a mother “speeds up” if the physician leaves and delivers unexpectedly. The use of solution of pituitary is dangerous, and forceps should be used most rarely. I would appreciate your opinion on these points also.

Since the majority pay little or nothing (the patient cited has never paid me a cent), a physician cannot afford to handle many else he would go into bankruptcy from neglecting paying patients while absent on his maternity calls. Is there any method of “speeding up” a delivery that is perfectly safe to both mother and child? I would rather spend twenty-four hours at the bedside than run even a risk of killing either, or, for that matter, of even causing avoidable damage to the birth canal or infant. Perhaps the best solution would be to hospitalize all rural obstetric cases. In my own little practice I have, during the past year, refused all “last minute” maternity calls; I mean those who have neglected at least reasonable antepartum care. I have done this not only for my economic protection but also because I feel that such action in this state is necessary to train the public in the matter of antepartum care. Many of the counties provide visiting nurses, and the state pays a small fee to the physician who cares for the indigent mother. If the physicians continue to answer “last minute” calls the people will continue to neglect antepartum care and the efforts of the state and of medicine will be counteracted.

RURAL PRACTITIONER, New York.

AN OBSTETRIC CASE

A white woman, aged 38, a housewife and business woman, a primipara, had been given antepartum care by her own physician. Pregnancy was uneventful. Abdominal flatulence had recurred for years regardless of treatment. Labor began at the thirty-sixth week, according to the menstrual history. A physician who had never even heard of the patient was called in the absence of the engaged physician at 2:30 a. m.

First Stage (sixteen and one-half hours): According to the history at the bedside, the membranes had ruptured spontaneously, with frequent expulsion of small quantities of fluid, after the first half hour. The physician was called after four hours. At four and one-half hours, palpation was practically impossible because of abdominal distention. The cervix, by rectal examination, was one fourth dilated; the fetal heart rate was 160, in the left lower quadrant. Pains of from fifteen to forty-five seconds’ duration occurred at average intervals of from five to six minutes, moderately strong, from four and one-half to ten and one-half hours and from twelve and one-half to sixteen and one-half hours, a two hour relatively quiet interval between. At the ninth hour aseptic vaginal examination revealed the cervix two thirds dilated; the fetal head was in left occipito-anterior presentation and no disproportion was evident. At the twelfth hour sodium amylal, 1½ grains (0.2 Gm.), was administered. At the end of the first stage the patient was somewhat tired but the pulse was good.

Second Stage (three and one-quarter hours): The beginning was judged by increased strength and frequency and the bearing-down character of the pains. After one hour the head was on the perineum. Pains were fairly strong, with a duration of thirty seconds, at intervals of from one to one and one-half minutes. At the end of two and one-half hours (one and one-half on the perineum) there was progress, but little on vulval inspection. The use of low forceps was considered. At two and three-quarter hours there was progress. At three and one-quarter hours spontaneous delivery occurred of an 8 pound 4 ounce (3,741 Gm.) infant in left occipito-anterior presentation. There was practically no bleeding.

Third Stage (about twenty-eight hours): No bleeding occurred and there were no pains. The abdomen was greatly distended and tympanitic;

palpation was practically impossible. There were sounds suggestive of a fetal heart with a rate of 164 in the left upper quadrant and what might be a fetal head or partially contracted fundus was indefinitely palpable in the right upper quadrant just above the level of the umbilicus. The abdomen was massaged frequently for two and one-half hours; large quantities of gas were expelled by the mouth and rectum; no bleeding occurred and there were no pains. The patient was tired. The possibility of the presence of a twin was considered. The cord stump and the vulva were protected by sterile dressings. The physician left (after eighteen and a quarter hours with the mother, except for a two hour interval during the first stage) with directions for immediate call if developments occurred during the night.

The night was uneventful; the mother was comfortable. Distention continued. There were no fetal heart sounds. The abdomen was massaged, without results. At 11:45 a. m., fluidextract of ergot, U. S. P., 15 drops, was administered. At 3 p. m. there were a few vague uterine pains. At 4 o'clock the ergot, 15 drops, was repeated. At 7 o'clock there were still no pains; the patient had passed about 30 cc. of blood. A modified Credé expulsion was attempted without success; the abdomen was very tender. The physician requested consultation (for anesthesia and manual removal of the placenta). At 9:30 p. m. the distention was markedly reduced. A semisoft uterus was palpable one fingerbreadth below the umbilicus, with a hard ring transversely across the lower segment. Under ether anesthesia, with full aseptic preparations, an intact placenta was expressed. Solution of pituitary 0.5 cc. was administered. The posterior vaginal wall was sutured. The fundus was well contracted. The physicians left at 11:40 p. m.

Puerperium: On the second day the patient was comfortable. The temperature was 100.4 F. A cathartic was ordered.

On the third day the patient was feeling well. The temperature was 101, the pulse 84 and good. In the evening the temperature was 104.2. Orders were given for fluids, alkaline drinks, a cathartic, a light diet and no visitors.

On the morning of the fourth day the patient was feeling well. The temperature was 102, the pulse 84 and good. The breasts were normal. There was a thick yellow-brown vaginal discharge. Orders were given for a fluid diet, low vaginal irrigations with corrosive mercuric chloride 1:1,000, and removal of the infant from the breast. The afternoon temperature was 102.4. The patient complained of flatulence and discomfort. Orders were given for elevation of the head of the bed and insertion of a rectal tube.

On the fifth day the patient was feeling well. The temperature was 100.8, the pulse 90 and good.

On the sixth day the patient was feeling well. The temperature was 100, the pulse 81 and good.

On the seventh day the patient was feeling well. The temperature was 100, the pulse 81 and good. Orders were given for a soft diet.

On the eighth day the patient was feeling well. The temperature was 99, the pulse good.

On the ninth day the patient was feeling well. The afternoon temperature was 98, the pulse 81 and good. Lochia was moderate. Orders were given permitting a few visitors and a moderate diet.

On the tenth day the mother was not visited. No telephoned reports were received.

On the eleventh day the patient's condition was very good. The afternoon temperature was 98.4, the pulse 74 and good. Abdominal distention was only moderate. The fundus was not palpable. The breasts were normal. Orders were given for a regular diet and sitting up in bed.

On the twelfth day the patient's condition was very good.

On the thirteenth day the patient's condition was very good. Orders were given that the patient might be out of bed gradually and might be up and dressed on the fifteenth day. The mother was discharged, with orders to report at the office for postpartum examination after six weeks. She has never reported.

Note: The breasts were permitted to dry, supported, as repeated attempts to nurse the infant resulted in gastric upsets. On the twelfth day a diagnosis of pyloric stenosis was made. It responded to gruels (the father refused to administer atropine, and later gruels and preferred condensed milk). The patient was apparently normal after the fifteenth day. She was discharged conditionally, on the twentieth day.

ANSWER.—1. It is scientifically and ethically wrong and economically unfair for any one to speed up a labor to save his own time, for his own convenience or to increase his fee. Without doubt the continued high maternal mortality in the United States and other countries, where such a practice is growing, under various alibis, is in part due to such interference with the natural processes of labor. The use of pituitary and of quinine, the routine rupture of the membranes, and other procedures are responsible for a certain percentage of the mortality of the new-born and of puerperal infection in addition to the damages which the cervix, the pelvic floor and the baby's brain so often suffer.

2. It is probable that an imbalance between the sympathetic and the autonomic innervation caused the prolonged first and second stages, and this might also explain the uterine inertia of the third stage. In such cases atropine might have hastened the labor. A low forceps operation on this patient, after the head had been down on the pelvic floor for one or two hours, would have been justifiable.

3. Regarding the third stage, some difference of opinion exists as to whether a placenta should be left in the uterus, that is in the absence of hemorrhage of course, for any extended period of time. Ramsbotham relates a case in which the placenta never came away and was either absorbed or discharged piecemeal in the lochia.

Polak in 1922, in cases of retained placenta, advised tamponade with washed iodoform gauze, leaving it in place for from twenty-four to thirty-six hours, and others, usually older authors, have said that there is no hurry about removing the placenta, in the absence of hemorrhage; but this was in the days when manual removal of the placenta was attended with great danger from infection.

Nowadays it is considered better practice to empty the uterus, at least before three hours has passed. Aseptic and antiseptic preparation, rubber gloves and relaxing anesthetics render this operation safe.

Years ago there were many cases of incarcerated placenta following the administration of ergot. This practice therefore was discarded. The amount administered here probably would not have caused stricture of the uterus. Pituitary occasionally acts in the same way as ergot by incarcerating the placenta but not sufficiently often to contraindicate its administration.

4. As for the economic aspects of long obstetric cases, it is notorious that obstetrics is the hardest, most time consuming and least remunerative specialty in all medicine. Perhaps the doctors themselves are to blame for permitting this state of affairs. In the cities the question of caring for the indigent or middle class is easily settled by sending the patient to a hospital, although in many hospitals the service is no better and not as safe as the woman can obtain in her own home if her case is properly managed. Nowadays the automobile has annihilated distances and it would take a man less time to reach a patient 30 miles from his office than it used to require to go 8 miles in the days of the buggy.

Presupposing that a woman has been given proper antepartum care and goes into her labor in good health and that no indication of complications can be detected at the first thorough examination, medical and obstetric, a patient is probably safer in the hands of nature alone than in the hands of those who speed up cases with pituitary, quinine and rupture of membranes. But this is not an argument for reducing the amount and quality of medical care rendered a woman during labor. Civilization has increased the pain and perils of childbirth. We should always strive toward the ideal, and this means at least two physicians and one trained nurse and a perfect maternity hospital. Such attention is economically impossible for the majority of women and it is comforting to know that, with the aid of nature and employing all the knowledge that modern science has given the obstetrician, he can obtain thoroughly satisfactory results with the means at his disposal if he is willing to make the effort to use them.

5. Regarding the refusal to attend last minute maternity calls, it is always the best practice to answer every maternity call that comes in. Educating the public must be done by example, by word of mouth, by pamphlets and leaflets, and in similar ways, always remembering that one has to keep hammering all the time and that progress is slow.

ERYSIPELAS

To the Editor:—A man, aged 27, a butcher, at the age of 15 suffered an infection of the left hand, which required an incision and drainage and which left him with contraction of the tendons of the fourth and fifth fingers of the left hand. Since then every few years he gets attacks of lymphangitis associated with chills and fever. The area of redness starts from a slight abrasion of the finger and extends as a rule to the shoulder and is accompanied by axillary adenitis. Two years ago this eruption spread from the hand to the back of the thorax. At that time he was very ill, and at first a diagnosis of sepsis was made. He was given two blood transfusions, which did not stop his chills or high fever and spread of the eruption. The diagnosis was then changed to that of erysipelas migrans. He was given two injections of erysipelas serum, which immediately cleared up his condition. This year he again suffered an attack, which began on the same hand as a lymphangitic condition with tender palpable glands in the axilla, and severe chills with a temperature of 103, and which spread next day to the back of his thorax, the area of redness being located below the angle of the scapula to the costal margin and to the spine. He was again given an injection of erysipelas serum, which was repeated in twenty-four hours, and the condition immediately cleared up. But four days later he developed a severe urticarial rash, which cleared up in twenty-four hours after a few injections of epinephrine and local applications. Could you suggest anything to prevent these attacks, which, because of his trade, he is liable to suffer again, and which will be more difficult to control in view of the fact that he became sensitized to the serum? Please omit name.

M.D., Brooklyn.

ANSWER.—An attempt to desensitize the patient can be made as outlined in THE JOURNAL, June 9, by Leona M. Bayer, in the article on desensitization to insulin allergy. If erysipelas recurs before this can be done, it can in all probability be controlled by ultraviolet treatment or by treatment with roentgen rays. While a few authors complain of inability to control erysipelas with ultraviolet rays, the great majority seem to have been successful and are enthusiastic about the method. Czepa

(Zur Behandlung des Erysipels mit der Quartzlampe, *Wien. klin. Wchnschr.* 35:564 [June 22] 1922), reports 100 cases mostly on the face. In this location, a prompt cure was obtained in all cases. A few cases on the trunk were refractory. He gave a fairly strong erythema dose on three successive days, the second and third doses somewhat larger than the first, which he described as ten minutes at 80 cm. with a not too old burner. The eyes were protected only by the closure of the lids. The temperature dropped promptly and the disease stopped spreading. The only after-treatment was cool wet dressings of very dilute solution of aluminum acetate or 0.1 per cent resorcin water. The second and third treatments were given as a precaution against relapse.

Josef Becker (Die Wirksame Dosis bei der Quartzlampebehandlung des Erysipels, *München. med. Wchnschr.* 74:497 [March 25] 1927) found that one and a half times the erythema dose was efficient. He also repeated this dose as a precautionary measure on the second and third days. For those without a dosimeter, he recommends from nine to twelve minutes at a distance of 100 cm. (40 inches) with a good burner. He warns against too strong a treatment.

As proof that the prompt subsidence of the disease after this treatment is no mere coincidence, he cites a case of erysipelas of the face in which the temperature fell promptly, the general condition improved after the treatment, and the disease ceased to spread except in one spot behind the ear, which had escaped the first treatment. This continued to spread but yielded promptly to direct treatment.

Roentgen treatment of erysipelas is also highly successful. Most of the writers have used about one erythema dose, 300 roentgens, but von Battingen reports that one-fourth erythema dose, 75 roentgens, is successful, repeated on the following day if thought necessary.

G. C. Andrews (Diseases of the Skin, Philadelphia and London, W. B. Saunders Company, 1930, p. 537) reports that fractional doses of x-rays have in two long standing cases of recurrent erysipelas stopped the attacks completely for more than three years.

It would seem, then, that the case under discussion may be successfully treated even though attempts at desensitization fail.

POSSIBLE BENZENE POISONING IN PAINTER

To the Editor.—A painter who had been engaged in doing glazing for five days in confined quarters without ventilation was attacked with a severe dizziness so that he had to quit working. For the past four weeks he has been under my care. His chief complaint is dizziness, which is particularly pronounced on arising from his bed in the morning but occurs also at various periods. He may go around for two or three days without any pronounced dizziness and then have one day in which there is a severe recurrence. In addition to the main complaint of vertigo, which makes it absolutely impossible for him to do his work, he also complains of general weakness and particularly of muscular weakness of the lower limbs. He also complains of occasional spells of dyspepsia and lack of appetite. Physical examination reveals considerable pallor and at times a tendency to jaundice. Occasionally the sclera and the skin are entirely clear, but in most of the visits I find a light yellowish tinge throughout the skin, particularly visible in the sclera. Otherwise the examination is negative. A blood count reveals a secondary anemia with about 3,000,000 red cells, and a white count of about 4,000 cells. The differential revealed about 60 per cent of polymorphonuclears and 40 per cent monocytes. There is no evidence of any basophilia or stippling of red cells. The varnishes used in the glazing contain turpines and benzene. I am impressed that the condition is one of granulocytopenia due to poisoning with benzene. Do you believe that this conjecture is in agreement with the symptoms presented? What would you suggest for the treatment in this case? It is evidently not a case of plumbism. Please omit name.

M.D., Ohio.

ANSWER.—In view of the statement that the materials utilized by this worker contain benzene, it seems appropriate to believe that benzene poisoning exists. Especially is this suggested by the anemia and the leukopenia. By way of control and treatment of this condition the following suggestions are made:

1. The worker should be removed from any further exposure to benzene.
2. General measures should be instituted, directed to the prevention of infection and the elimination of the anemia.
3. Exposure to natural or artificial sunlight has proved of value in these milder cases of benzene poisoning.
4. Some good results possibly may arise from the administration of liver extracts. These should be used as in the case of any other form of anemia.
5. Lecithin emulsion (5 cc. of a 10 per cent strength) has been administered intravenously to advantage.
6. Great caution should be exercised in connection with such procedures as dental extraction and tonsillectomy.
7. A high calcium intake in food is commendable.

GLANDULAR DYSTROPHY

To the Editor.—A married woman, aged 27, complains of a menstrual and intermenstrual disorder. The patient is obese, weighing 160 pounds (72.6 Kg.). Her height is 5 feet 2 inches (157.5 cm.). She states that she began her menstrual periods about fifteen years ago. Then the periods were normal, occurring every twenty-seven to twenty-eight days, with a duration of four or five days. Two years later she had scarlet fever. Her periods stopped for four months. Following this amenorrhea she began to have irregular periods, which occurred every two to three months. Ten and one-half years ago she had nine months of amenorrhea, for which she saw a physician. She was given ovarian extract, which started an irregular flow. This type of menstrual flow differs from the previous ones in that it lasts between two weeks and two months, weakening the patient considerably and causing her much left lower quadrant pain. An endocrinologist has tried corpus luteum and anterior and posterior pituitary medication, with inconstant alleviation of symptoms. Theelin was tried, with no relief. One gynecologist told the patient that she had degeneration of both ovaries; another said that she had cysts of both ovaries. Associated with the menorrhagia, the patient has noticed a marked body and facial hirsuties. The latter feature has become so prominent that social contacts are embarrassing. Late, with oral administration of 5 grains (0.3 Gm.) of whole ovary daily, the patient has not menstruated for one month. Can you offer any suggestions as to further treatment and diagnosis? Do you think the patient will ever be able to conceive?

M. I. GOLDIN, M.D., Eloise, Mich.

ANSWER.—The story is that of a woman who is the victim of a pituitary deficiency. This evidently involved first the growth hormone of the anterior lobe and began during her growing years. This is indicated by her short stature. One would speak with more assurance along this line if more of the family history had been given, particularly the height and weight of the parents and siblings. It would also be helpful to know the age of onset of the obesity.

In spite of the absence of that information, the statement can be made with considerable assurance that following the original deficiency of the growth hormone there was later an involvement of the gonadotropic hormones and of some other factor in the pituitary. This further deficiency was probably brought about by the damage wrought by scarlet fever. This disease seems to exert a selective influence on the pituitary, and deficiencies of that organ frequently follow attacks of this disease. A further possibility is that the scarlet fever was accompanied by a temperature sufficient to damage the ovaries directly and that this also was a contributing factor in the amenorrhea that followed the scarlet fever.

The menorrhagia that now troubles the patient is probably due to a lack of the luteinizing factor or hormone of the anterior lobe and probably can be controlled by administering the anterior pituitary-like principle from the urine of pregnancy. This should be given in doses of 1 cc. (from 100 to 125 rat units) or more daily until the bleeding is controlled. Light, so-called stimulating doses of the x-rays applied to the pituitary and ovaries might possibly be helpful, but this treatment entails a certain hazard and should be used only as a last resort. It is unlikely that the oral administration of whole ovary will be of any benefit.

The facial hirsuties is probably due to a pituitary disturbance but raises the question also as to whether it may not be due to an involvement of the suprarenal cortex. It should be recalled that tumors of the cortex occurring in adult women are associated many times with amenorrhea, with hirsuties and with an elevated blood pressure. Other symptoms of this disorder are acne, loss of hair on the head, increased muscular development and a deepening of the voice—a decrease in the female and an increase in the male attributes of the individual. Prolonged treatment of such cases with preparations of the anterior lobe is frequently followed by pregnancy.

SCLERODERMA OR RAYNAUD'S DISEASE

To the Editor.—I am much interested in a high school boy living across the street from me, who is greatly handicapped with Raynaud's disease. His fingers are of stony hardness, flexion and extension are limited, pressure sores appear over the knuckles and on the finger tips, and throughout the winter the hands are blue or purple almost continuously. This summer the fingers are more inflexible than last, although he can drive a car. I would like particularly references to the literature concerning treatment, surgical or medical, possibly a critical review by some one or group of individuals, who have reported a number of their own cases. Also who are some of the neurosurgeons in the Midwest or East who have had a large experience with the disease? M.D., Ohio.

ANSWER.—Obviously the diagnosis in this case is scleroderma involving the extremities: acroscleroderma or sclerodactylia. The onset of this disease is frequently initiated with vasospastic disturbances reflected in color of the skin, such as is seen in Raynaud's disease. Frequently the face and upper part of the thorax are involved in this process. It seems that the primary disturbance involves the smaller arteries and arterioles, with quantitative diminution in the number of vessels and in the circulating blood in the affected parts. The ulcers on the ends of the fingers may contain particles of

calcium from terminal phalanges. This can be shown in the roentgenogram. Arteriography demonstrates an occlusive lesion of the digital arteries and evidence of spastic phenomena. Treatment in the later stages of the disease is not satisfactory. In the earlier types of the disease, in which marked involvement of the joints, deformities and excessive fibrosis of the skin are lacking, cervicothoracic sympathetic ganglionectomy affords the best opportunity for some improvement in the hands and face. If present in the feet, lumbar ganglionectomy is used. The amount of improvement is variable, but in all cases some improvement has been observed. By this procedure the vasomotor control of the vessels of the hands is eliminated, and the maximal flow of blood is permitted to reach these parts. Medical treatment consists of physical therapy and injections of foreign protein to produce systemic fever. This should be continued over a considerable period of time, if well tolerated. In a small percentage of cases, definite progression occurs in spite of all treatment. Death occurs from exhaustion; pathologic changes are found in the heart.

PROVOCATIVE WASSERMANN TEST

To the Editor—In a syphilitic suspect whose blood Wassermann reaction is negative, what is the value and the technique of a provocative Wassermann test? What interval of time should elapse between the drug given and the taking of the blood specimen? M.D., Tennessee

ANSWER—The provocative Wassermann test is of value in diagnosis in patients with a definite syphilitic infection in the past, whether treated or untreated, but with a negative blood Wassermann reaction, in about 10 per cent of the cases in which it is tried. When the blood Wassermann reaction is negative in the presence of a lesion thought to be syphilitic, or if there is persistent partial fixation even in the absence of suggestive lesions, a decision as to whether the patient has syphilis may sometimes be made by observing the effect on the blood Wassermann reaction of a single injection of arsphenamine 0.3 Gm or of neoarsphenamine 0.6 Gm. The blood Wassermann test should be quantitatively titered at the time of the injection and every other day thereafter for fourteen days. The test is positive if reagin appears in a previously Wassermann negative blood, or if it increases sharply in amount in a blood previously doubtful or positive. The increase of reagin, if it occurs at all, begins about the third day and reaches its maximum about the tenth day with subsequent subsidence to the original level.

Though the provocative Wassermann test is of value as a diagnostic procedure, it is of no value whatever as a criterion of cure. The test is significant only when positive, absence of provocative effect does not signify freedom from syphilis; and in late syphilis, even though previously untreated, the test is much more often negative than positive.

The provocative effect is observed much more frequently in patients with either early or late syphilis in whom the blood Wassermann reaction is already positive at the time of the first arsphenamine injection. It can be demonstrated in the majority of such individuals by means of quantitative titrations of blood serum in the test. The increase in Wassermann titer reaches its maximum between the fifth and tenth days, after which the titer usually subsides promptly to or below its original level.

LESION OF VULVA

To the Editor—I have a patient who reported to me for examination, May 8. She was three months pregnant and there was a lesion at the fourchette involving the left labium majus. The lesion was about a little more than five eighths inch vertically and went down into the fourchette, presenting the appearance of a tear. It bled much and is still very vascular. Various local applications were made. It was also cauterized or, rather, phenol (carbolic acid) full strength was applied and did stop bleeding for a while. The patient stated that she discovered the lesion two weeks before I saw it and tried to treat it herself but made it worse. Three Wassermann reactions have been negative and there are no constitutional symptoms that might suggest a syphilitic infection. I am unable to reconcile it with the various lesions usually encountered in that position or place. The part of the labium seems to be healing slowly from its outer border, but deep into the fourchette the condition still obtains and bleeds readily on handling or movement. No constitutional treatment has been given because of lack of indication. There is also a degree of leukorrhea that might contribute to the sluggishness to heal. The patient is sensitive to intercourse, and access to the deep parts is difficult. Kindly advise me in this case. The patient is a Negress, aged 28, a primipara. Please omit name.

M.D., South Carolina.

ANSWER—In the differential diagnosis of the lesion described, a number of causes must be considered. The lesion may be the result of trauma from coitus or other reason, but such injuries usually heal rapidly unless they become infected. In spite of the negative Wassermann tests and absence of consti-

tutional symptoms, a chancre must be considered. Such a lesion usually has an indurated edge with shallow sloping sides, and the tributary lymph nodes are shotlike. Chancroids are usually multiple, they have soft, undermined edges, they are tender, and they are generally accompanied by buboes in the groin. Diphtheria, while rare, must be considered, but the lesion in most cases is covered by a thick, gray, adherent membrane, and there is fever and usually a history of a similar infection in the throat. The diphtheria bacillus can be isolated readily from such ulcerative lesions. There is a possibility of local tuberculosis, but in most of these cases there is evidence of a similar infection in other organs, the ulcer is slow growing, and its base is shotlike. The lesion may be granuloma inguinale, which occurs almost exclusively in Negroes. In such cases Donovan's bacilli can be isolated and the lesions yield readily to antimony and potassium tartrate and to fuadin. In spite of the patient's age, an early carcinoma must be considered. In such ulcers the border is hard and elevated and the lesion is friable and bleeds easily. In the case cited an effort should be made to detect diphtheria bacilli, Ducrey's bacilli, tubercle bacilli, Donovan's bacilli and spirochetes. Furthermore, a small piece of tissue should be removed and studied microscopically. This will prove or disprove the presence of carcinoma and may reveal the cause of the lesion.

DIAGNOSIS OF FACIAL PARALYSIS

To the Editor—A man, aged 38, in rugged health, with a completely negative past history of illness or injury, suddenly became dizzy while walking along the street and within a few hours developed a left-sided blindness, a left facial paralysis and a complete left hemiplegia. This was accompanied by headache and a slight ringing sensation in the ears. My examination was made approximately one month after the onset. About five days previous to my examination he had had a partial recovery, but examination showed an involvement of the right optic tract. The reflexes were not disturbed. The blindness was to objects on the left, a homonymous hemianopia. The facial paralysis involved the lower peripheral fibers, but retention of the ability to wrinkle the forehead on both sides was maintained. There was a complete left hemiplegia, presumably an involvement of the right pyramidal tract about the decussation. The tendon reflexes of the arms and legs were both increased and the pathologic reflexes (Babinski, Chaddock) were present. I am presuming that the patient had a thrombus; his blood pressure has been normal throughout, repeated blood Wassermann reactions have been negative, though no spinal test has been made. The question arises as to where the thrombus was or where the lesion occurred, since the right optic tract must be involved back of the supercolliculus, back of the external geniculate body and back of the pulvinar. It is easy to associate this with a lesion of the right pyramidal tract, but it is not so easy for me to understand why the left facial would be involved, on the assumption that the patient has a single lesion. The textbooks are rather confusing as to the amount and degree of supranuclear decussating fibers of the facial. Would it be possible for this man to have sufficient right supranuclear fibers, decussating to the left, to produce such a paralysis? Please omit name.

M.D., Oklahoma.

ANSWER—The involvement of the face described is of the type that is common in central (pyramidal) lesions and is not due to involvement of the peripheral facial nerve. In a general way it may be said that movements that are essentially bilateral in character, such as those of the upper part of the face and of the large trunk muscles in breathing, are represented in the cortical centers of both sides of the brain, whereas movements that are essentially unilateral are represented mainly only in the motor center of the opposite hemisphere of the brain. This explanation is offered for the clinical observation that a lesion of one pyramidal path affects severely movements that are largely unilateral and affects only slightly those that are mainly bilateral. A lesion in the hinder part of the internal capsule may involve not only the pyramidal fibers for unilateral movements of the opposite side of the body but also the fibers of the optic tract. The sudden onset does suggest a vascular lesion, and the development within a few hours might point to a thrombus. In a man, aged 38, the most common cause for such a vascular insult is syphilitic arteritis. In the absence of evidence of this infection, care should be taken to exclude the presence of a neoplasm in which a vascular lesion has occurred.

PREVENTION OF DISEASE IN TROPICS

To the Editor—We are planning a cruise to South America, spending three days in British Guiana. My wife and two daughters have never left Wisconsin. Can you advise me the best drug method of malarial prophylaxis, and a simple method of purifying drinking water, other than boiling? Would carbonated beverages be reasonably safe? We are a bit afraid of malaria and typhoid.

M.D., Wisconsin

ANSWER—Drug prophylaxis is not satisfactory, as in most cases it serves to inhibit clinical manifestations without preventing infection. Although not as extensively tested as the older compounds, atabrine (in curative doses of 0.2 or 0.3 Gm.

daily) promises to be a valuable drug for prophylaxis and is comparatively nontoxic. However, atabrine even in small daily doses of 0.1 Gm. will produce a yellow coloration of the skin after a variable time. This disappears fairly promptly on withdrawal but this may be an objectionable feature to the use of the drug as a prophylactic. For such a short stay the best method of malaria prophylaxis is probably to sleep under a good mosquito net or in screened quarters. It is also advisable to be in screened quarters during the hours immediately preceding and succeeding sunset, as these are the most dangerous hours of anopheline flight. Boiling water is undoubtedly the best method of rendering it safe for drinking. Many of the portable methods of purifying water are too cumbersome for such a short trip and some of them are probably not effective for certain animal parasites. Next to boiling water it is safest to drink such liquids as weak tea. There are also generally available in these parts spring water bottled in the United States, which is safe if one always makes sure that the seal on the bottle is unbroken. In general, carbonated beverages are reasonably safe, but this is due largely to care in manufacturing and to the fairly rapid death of non-spore forming pathogens. Sometimes, however, local products are so unhygienically prepared and so quickly marketed that they are not safe. Beverages that are carbonated by fermentation, such as beer, are safe. For protection against typhoid, vaccination should be considered.

DIABETES, TUBERCULOSIS AND ARTERIOSCLEROSIS

To the Editor:—I have a patient with diabetes and tuberculosis. He was admitted to the hospital in December 1932 with a minimal amount of tuberculosis affecting the right lung, but his diabetic condition, previously undiagnosed, was very severe. Acidosis developed immediately after admission and he came uncomfortably close to death's door. Jan. 12, 1933, he weighed 101 pounds (46 Kg.). At the age of 32 his height is 6 feet 1 inch (185.4 cm.). His condition improved steadily, so that during the summer months he was transferred to the "shack." His weight increased to 152½ pounds (69 Kg.) but at present it averages 136 (62 Kg.), about 10 pounds (4.5 Kg.) more than his best weight previous to admission. The point now is that the condition of his feet is preventing his return to work. Especially during the evening he complains of his feet tiring easily and painings so severely at times that he cannot walk. Both feet show marked sclerosis of the blood vessels, the pulse not being obtained in the dorsalis pedis of the left foot and but poorly in the right. This complaint began soon after the patient began to walk after being confined to bed for some five months. A consultant from Hartford suggested a high carbohydrate diet. This was tried with no avail, and at the request of the patient the former diet was reinstituted, which with some changes is at present protein 95 Gm., fat 192 Gm., carbohydrate 166 Gm., the high calory diet being protein 105 Gm., fat 150 Gm., carbohydrate 220 Gm. Immersions in hot and cold water, and cod liver oil rubs have been tried without success. Have you any suggestions to offer? I realize that the foregoing is rather short in a desire to avoid too many details. I neglected to say that the insulin dosage is breakfast 13 units, dinner 5 units and supper 8 units.

VIRGIL F. NEUMANN, M.D., Norwich, Conn.

ANSWER:—Neuritis on an arteriosclerotic basis would appear to be the cause of the pains in the feet. The marked arteriosclerosis in a 32 year old patient with diabetes of not more than two years' duration is striking and perhaps might be related to the gain of 50 per cent of body weight in a short period. One would like to know the fasting cholesterol value.

Is the patient taking alcohol?

The prognosis of diabetic neuritis is almost invariably favorable, although usually requiring months rather than weeks and sometimes even a year for recovery.

The avoidance of extremes in diet, thus, carbohydrate not over 175 Gm., protein 100 Gm. and fat from 100 to 130 Gm. according to retention of body weight, would seem indicated along with insulin sufficient to control the diabetes. Green vegetables, tomato juice, a dessertspoonful of cod liver oil and avoidance of any extremes in local treatment are the indications together with the guaranty that eventually recovery will follow.

USE OF CALCIUM INTRAVENOUSLY—CALCIUM IN TUBERCULOSIS

To the Editor:—My local drug supply house informed me that various preparations of calcium intended for intravenous injections have recently been withdrawn from the market. They presume that this has been due to instability of precipitation. I will be much obliged to you for the latest information as to the status of intravenous calcium therapy, especially for tuberculosis. Would it be better for me to prepare fresh solutions of calcium in my own laboratory immediately before the injections, and if so, what preparation should I use and how should it be made up and given?

G. P. LAWRENCE, M.D., Westerville, Ohio.

ANSWER:—We are not aware of solutions containing calcium intended for intravenous injections having been recently withdrawn from the market. Some time ago it was found that calcium gluconate solutions would precipitate, particularly in the cold, but by warming would be redissolved. To overcome

this difficulty one firm is marketing its solution in admixture with calcium lactobionate. The Council has not reported on the use of calcium in the treatment of tuberculosis. In general, the evidence has not borne out the early enthusiasm for such therapy, although it may have a limited field of usefulness. Mayer and Wells concluded that there is no acceptable clinical evidence for the value of calcium therapy in tuberculosis. Their animal experiments failed to show that calcium therapy favorably affected the course of the disease. Calcium compounds have been used in tuberculosis to remedy calcium deficiency, to lessen inflammatory exudate, to favor calcification of lesions and to lessen sweating and diarrhea; but it is not considered an essential remedy by critical students of the subject.

PURPURA SIMPLEX

To the Editor:—A woman, aged 28, unmarried, complains of a reddened pin point to pin head sized lesion beneath the skin above her ankles, which appears every summer. Heat from a motor car will also produce these lesions. She is a blonde. The Wassermann reaction, urinalysis and blood counts are normal. The tourniquet test is positive, although the spleen is not palpable. Can you suggest any way of preventing these lesions? Kindly omit name and address.

M.D., California.

ANSWER:—There are a number of points concerning the description of these lesions that would be of interest. The question as to whether they are macular and fade on pressure or definitely purpuric cannot be settled from the description. In either case they fall into the erythema group. In this group one may have different clinical pictures, depending on the amount of vascular permeability. It is the latter factor that determines the morphology of the lesion. From the data submitted the patient appears to have a condition known as purpura simplex. Individuals with this condition are otherwise in good health, show no spontaneous mucous membrane bleeding and have purpuric lesions only on the most dependent portions of the body. The direct causative factor is an abnormal vascular permeability, which is brought to light spontaneously by such factors as are given in the history, or it may be induced by the tourniquet test. The coagulation, bleeding and cloth retraction times are normal in such cases. Given this constitutional background, a number of precipitating factors may produce this symptom, among which are endocrine disturbances, particularly during the menstrual cycle, infection and external irritants. In the absence of such factors the following regimen may be of benefit: The diet should contain adequate amounts of foods that contain vitamin C. Factors producing stasis in the dependent parts of the body should be removed and measures designed to improve circulation should be instituted. Contrast baths are often combined with the use of mild astringent lotions, and in some cases definite benefit may be observed. Calcium preparations are often prescribed, but the value of such therapy is questionable. Cases of this type have a favorable prognosis.

POSSIBLE BENZENE POISONING WITH GRANULOCYTOPENIA

To the Editor:—Can you tell me whether the solvents for Plastic Wood and Valspar contain benzene or any of the allied substances? A patient who had had several attacks of granulocytopenia, definitely known to be due to amidopyrine, had refrained from all such drugs with good results, i. e., had had a normal white cell count for some months. After he had been exposed to the fumes of these two substances in a closed room, the white cell count fell to 2,073, with 27 per cent neutrophils. No other cause could be found and there have been no further attacks for about a year. I thought that perhaps the bone marrow had become very sensitive to these agents. Please omit name.

M.D., Virginia.

ANSWER:—The present reply refers to no specific product but instead to the general classes of substances into which fall the two items mentioned in the query.

Varnishes prior to thinning consist of various gums cooked up with oils, such as China wood or linseed. Ordinarily varnishes are thinned with petroleum naphtha and turpentine. However, they may be thinned with solvent naphtha, which may contain approximately 50 per cent of benzene. Since spar varnishes represent a high type of varnishes and since solvent naphtha instead of petroleum naphtha is more likely to be used in high type varnishes, exposure to benzene probably takes place frequently. This is true for the manufacture of varnishes as well as for their application. Plastic fillers, of which plastic wood is one variety, may be made from a variety of substances, such as saw dust, cheese and synthetic resins. These solid materials are mixed with some quick drying substance, such as varnishes, naphthas and various alcohols, including methanol. Here again opportunity may arise for exposure to benzene or benzene-like substances. The assumption implied in the query that benzene poisoning exists or has existed is within reason.

IMPOTENCE AFTER INJECTION FOR INGUINAL
HERNIA

To the Editor:—I have a patient, aged 58, with impotence. The blood pressure is normal and the Kahn reaction negative. Two and a half years ago he had a fracture of the seventh cervical vertebra and also some injury to the base of the spine but no fracture. In April 1933 he had an operation for double hernia following some injection treatment, which produced a great deal of scar but no cure of the hernias. The surgeon said that the scar was very dense. The roentgenogram taken about one year after the accident shows some scar in the region of the coccyx. His wife died following this accident and he remarried last December. He was potent for about one month, when he noticed that his testicles were getting smaller. On examination I found the right testicle to be about the size of an ordinary peanut and the left about twice that size. He shows no other symptoms along the urinary tract or otherwise except that he tires more easily than ordinarily. I would be pleased if you could give me the cause of testicular atrophy in such a case. The man is very well preserved physically and is alert mentally. Please omit name.

M.D., Michigan.

ANSWER.—In the absence of any pressure symptoms on the cord, such as paralysis or bladder symptoms, the spinal injuries can be excluded as a cause of either the impotence or the atrophy of the testicles. It is likely, however, that the injections he received for his hernias cut off or greatly interfered with the blood supply of the testicles. This result is at times seen in poorly done varicocele operations as well as in other operations on the spermatic cord in which the arteries which supply the testicles and which accompany the cord are tied off. It may therefore be possible that the small testicles do not produce enough hormone and that impotence will result.

PARALYSIS AGITANS

To the Editor:—My wife fell about two years ago, injuring her spine in the lumbar region. This does not give her any pain or trouble, but she has developed paralysis agitans. I have consulted several colleagues. I am giving her a general tonic and scopalamine hydrobromide $\frac{1}{320}$ grain (0.4 mg.) once or twice a day, which seems to hold the condition in check. I have been thinking of light massage to the right arm and hand, which are affected; perhaps a light treatment of high frequency (violet ray) might be beneficial. Would you kindly let me know? If you have any other suggestions, I would appreciate them. She is 66 years of age. Is it beneficial to exercise the arm and hand or best to spare using them? Please omit name.

M.D., New York.

ANSWER.—Therapeutic measures in paralysis agitans that give the most relief are of a sedative nature, such, for example, as scopalamine and related drugs. In the general management in such cases stimulants and excitants, mental as well as physical, should be avoided, as they tend to aggravate the symptoms. The aim should be the provision of a quiet and monotonous routine, which is at the same time as satisfying and interesting to the individual patient as can be devised. Fatigue is harmful, and exercise and activity should be limited to avoid it. Stimulating massage of the muscles and undue exercise tend to aggravate the symptoms; light skin friction or vibratory massage will often give relief, though sometimes, owing to idiosyncrasies, they may distress the patient and should be avoided. Infra-red rays in doses that will not cause reactions in the skin and autocondensation may also be helpful. Such measures are of course palliative and not curative, but they may help to occupy the time of the patient and afford non-stimulating variety.

HERPES PROGENITALIS

To the Editor:—A man, aged about 50, had an attack of influenza several months ago from which he made a good recovery. But, accompanying the attack, a small group of vesicles formed under the glans penis near the frenum, typical of herpes progenitalis, which was rather severe and stubborn but finally responded to the usual treatment. Later a reddish macule about 2 by 3 cm. appeared on the upper surface of the glans, extending to the meatus and having some small, slightly elevated papules scattered throughout. It has disappeared once, or appeared to do so, to return again. There are practically no symptoms (itching or pain). I have advised alcohol locally—saturated solution of alum and Whitfield's ointment (mild), thinking it might be some form of tinea infection, which he has had ingrown at times. His health is good otherwise. What do you suggest as cause and treatment? Please omit name.

M.D., Arkansas.

ANSWER.—It is somewhat difficult to answer the query correctly from the description given. One would be inclined to think that the patient is having recurrent attacks of herpes progenitalis. Occasionally the lesions do not show themselves in a characteristic vesicle form; they may show up simply as a reddish macule or as a slightly elevated papule, such as the writer describes. The fact that they have disappeared and come back again would incline one more than ever to such a diagnosis. Why these began following the attack of influenza, it is impossible to state. It may have been simply coincidence. In some cases herpes progenitalis appears as the result of irri-

tation; for example, the use of rubber condoms. The use of hot potassium permanganate soaks might be tried for these attacks, and in case there is a long foreskin, it might be well to have a circumcision.

TREATMENT OF ANKYLOSED JOINTS

To the Editor:—What benefit can I expect a patient to derive from a course of diathermy treatments for ankylosed joints, resulting from acute multiple arthritis following an infected gunshot wound? A woman, aged 22, received the wound, May 12, 1933. She developed acute multiple arthritis, Oct. 9, 1933, and was in bed four and one-half months. She was in a plaster cast eighteen days, and the result was an ankylosed hip joint, ankle and elbow joint. The elbow was aspirated during the acute stage of inflammation and held firmly in splints for two months. Will diathermy applied to these stiffened joints now absorb the calcium deposits and give the patient normal motion in them? Roentgenograms show considerable calcium deposit but no destruction or erosion of the bony tissue. Please omit name and address.

M.D., Missouri.

ANSWER.—In the treatment of ankylosed joints, medical diathermy through the joints will not absorb the calcium deposits or increase the motion. There are two types of ankylosis, bony and fibrous, and it is not possible from the facts given to determine exactly the type of this case. The treatment of a bony or true ankylosis is surgical, and physical agents will not give results.

In fibrous ankylosis the principles of treatment are to increase the local circulation by luminous heat, hot whirlpool baths or medical diathermy. This is followed by stroking and kneading massage for the same purpose. When the process has quieted down and the pain has disappeared, stretching should be tried at intervals or with continuous traction. Great care should be taken to avoid reaction. If there is a reaction and continued pain, operation should be considered.

REMOVAL OF MOLE FROM CHEEK

To the Editor:—Please state the best way to remove a small flat mole from the cheek of a middle aged man. He wishes the procedure to cause as little scarring as possible. The mole is nonpigmented and there is no history of cancer in the family. There is only one mole in the middle of his left cheek and he thinks that it mars his good looks; besides, he sometimes cuts it in shaving. I have been asked to remove it for him. Kindly give me your answer. It extends slightly above the surrounding skin. He says it has recently grown larger. It is slightly redder than his reddish complexion. What does electricity offer? The mole is of about thirty years' duration. Kindly omit name.

M.D., West Virginia.

ANSWER.—There is no way in which the mole described can be removed without leaving some permanent defect. From a purely cosmetic standpoint the best results are obtained with skilfully applied electrolysis. Scalpel excision will eradicate the mole completely and there may be nothing but an inconspicuous linear scar. Electrodesiccation is likely to leave a disfiguring scar. Everything considered, probably the best method of procedure in this case is scalpel excision.

GONORRHEAL CERVICITIS

To the Editor:—A woman, aged 22, has had gonorrheal cervicitis for the past year and a half, starting with an acute gonorrheal vaginitis and cervicitis. The vaginitis responded nicely to local treatment. The cervix has been treated with frequent intracervical applications of silver nitrate in strengths up to 20 per cent and with intracervical application of the cautery. In addition, tampons and douches have been used. She has also had a course of gonococcus vaccine. In spite of all this, she still has a copious discharge from the cervix, which, however, has for a long time been negative for gonococci. Can you advise me as to the best methods for clearing up this discharge? The tubes and uterus are normal. Kindly omit name and address.

M.D., New York.

ANSWER.—Medical diathermy and the Elliott treatment are both entitled to consideration in the management of stubborn cases of this character. Their value is problematic.

A badly diseased endocervix should be given a long period of rest after each cautery treatment. Anxiety to obtain a favorable result has perhaps led to overtreatment. If two or three thorough endocervical cauterizations, at intervals of several months, do not yield the desired result, recourse to amputation of the cervix should be considered. A modified Schroeder operation is well adapted to these cases.

SOMNAMBULISM

To the Editor:—I should like to have some information on the treatment of somnambulism. W. W. BOLTON, M.D., Lansdowne, Pa.

ANSWER.—Somnambulism is usually not an actual walking in a state of sleep, because somnambulists commonly avoid obstacles, pick up objects and talk. The condition is allied to hysteria and a portion of the personality is split off or sub-

merged. A similar process may happen in normal persons in moments of intense concentration. As it is a disorder of the personality, treatment should begin with a thorough study of that personality with proper search for conflicts, fears, doubts, strains, false beliefs and the like. Satisfactory results may follow, depending on the data uncovered and the adjustment of the patient to new points of view and his cooperation in new habit formations. Each case is an individual life problem in itself and more specific directions cannot easily be given. Secondarily, of course, various mechanical means may be devised to confine the patient to bed or to produce some stimulus strong enough to "awaken" him if he gets out of bed. Avoidance of unusual fatigue or excitement is helpful and, in the case of a child, fairly constant guarding may be necessary.

INTERMITTENT NEGATIVE PRESSURE IN ENDARTERITIS

To the Editor:—Will you please send me information regarding a new treatment of which I have heard for obliterative endarteritis? The treatment requires an air tight chamber in which the foot and leg are placed. A motor driven pump is attached to the chamber and the pressure in the chamber is alternately diminished and increased to stimulate circulation. Where are the treatments given and who makes the apparatus?

H. ST. JOHN WILLIAMS, M.D., Poughkeepsie, N. Y.

ANSWER:—The intermittent negative pressure apparatus for increasing the circulation to the extremities in cases of occlusive arterial disease was developed independently by Louis G. Herrmann and E. M. Landis of the Colleges of Medicine of the Universities of Cincinnati and Pennsylvania, respectively. There are a number of articles in the medical literature by these investigators, representative of which are:

Herrmann, L. G., and Reid, M. R.: The Pavaex (Passive Vascular Exercise) Treatment of Obliterative Arterial Diseases of the Extremities, *J. Med.* 14: 524 (Dec.) 1933.

Landis, E. M., and Gibbon, J. H., Jr.: The Effects of Alternate Suction and Pressure on Blood Flow to the Lower Extremities, *J. Clin. Investigation* 12: 925 (Sept.) 1933.

Distribution of the apparatus is under the control of the investigators mentioned.

LUPUS ERYTHEMATOSUS

To the Editor:—In the treatment of lupus erythematosus what bismuth preparation, given intramuscularly, is used? Please give dosage and frequency. Kindly omit name.

M.D., New York.

ANSWER:—Lupus erythematosus can be treated in the same way, with the same dosage and the same preparation of bismuth that is used for the treatment of syphilis. As in the treatment of syphilis, care must be exercised to avoid over-treatment for, unless the human organism can respond to the stimulation of the drug, harm will be done instead of good.

A dosage of 1 or 2 cc. of a 10 per cent suspension of bismuth subsalicylate in a vegetable oil can be given in gluteal muscles once a week. Other bismuth preparations are valuable, differing in dosage and frequency of administration. The urine should be examined for albumin and casts before each treatment and the patient quizzed regarding any itchy eruption. A bismuth line at the margin of the gums is not a contraindication to further treatment pursued with proper caution.

The results from bismuth therapy of lupus erythematosus are less certain than those obtained by the use of gold compounds, but success is sometimes achieved with bismuth therapy after gold has failed.

HYPERKERATOSIS SUBUNGUALIS

To the Editor:—I have a case in which there is an overgrowth of the nail of the great toe. The overgrowth has been removed two different times and recurs after several months. This is probably a case of onychauxis or hyperkeratosis subungualis. Could you tell me how to cure this condition, or will it be necessary to remove the distal phalanx of this toe? Please omit name.

M.D., Illinois.

ANSWER:—The removal of the nail alone will not cure the condition, because the growing matrix or root will promptly form a new nail.

The proper surgical treatment is to remove the matrix as well as the nail. The matrix may be identified as the dense gray tissue lying beneath the proximal portion of the nail. It extends close to the bone and well back to the base of the distal phalanx. The entire matrix must be cut away or it will reform a deformed nail. The skin at the sides of the base of the nail may be incised and the skin flap turned back so as to expose the matrix. After removal of this tissue the flaps may be replaced and left without suture.

Healing will occur usually without complications.

QUINCKE'S DISEASE

To the Editor:—A man, aged 30, always well, was afflicted with Quincke's disease about two years ago. Since then he has had manifestations of this sickness in various parts of his body, almost continuously. He has received the usual medication but with little relief. Are there any new remedies for this disease? How about glandular therapy? Please omit name.

M.D., Massachusetts.

ANSWER:—The name Quincke's disease has been applied to two different conditions: angioneurotic edema and meningitis serosa. From the description given it is presumed that the former is meant. Angioneurotic edema is usually considered to be an expression of allergic reaction and for this reason atropine and epinephrine are often administered and may give relief. It is certainly advisable to have the patient tested for sensitivity to foreign proteins of various kinds and to search for foci of infection that might serve as a source of sensitivity to bacteria. It has also been thought that in some instances this skin disease is of psychogenic origin; if no sensitivity is discovered, it would be well to consult a psychiatrist.

VULVAR INFLAMMATION

To the Editor:—A young woman has a varying number of small lesions just outside the hymen, usually macular, sometimes papular, which are extremely tender to touch. These lesions come and go without treatment and apparently have no relation to menstruation. Can you suggest diagnosis and treatment? Please omit name.

M.D., Missouri.

ANSWER:—The most common vulvar eruption is an inflammation of the hair follicles. This may be produced by leukorrhea so slight in amount as scarcely to be noticed. The irritation of clothing, perspiration and chafing are other less common causes.

The hair may be clipped if unduly long, but it should not be shaved. Cleansing douches or nightly vaginal instillation of 2 or 3 cc. of 3 per cent tannic acid in glycerin suffice to control the lesions caused by leukorrhea.

PARANAVEL COLIC IN CHILDREN

To the Editor:—What is meant by paranael colic (pain about the navel region of colicky character, frequent in children)? I find nothing in the literature about it. Please omit name.

M.D., New York.

ANSWER:—Before a diagnosis of paranael colic is made, a number of conditions of more or less importance should be excluded. Appendicitis or its adhesions must be considered. Recurrent attacks of abdominal pain in the region of the navel are probably due to a downward pull on the ligamentum teres, which lies between the umbilicus and the liver. The condition is encountered most frequently in the active, overweight child with a pendulous abdomen.

Morse's article "Recurrent Abdominal Pain in Childhood" in the June issue of the *Journal of Pediatrics* mentions Pott's disease, pelvic disease, lead poisoning, epigastric hernia, intestinal worms, abdominal adenitis, tuberculous peritonitis, spasm of the intestine, redundant colon, constipation and indigestion.

EYE CONDITIONS OF WORKERS IN HAIR INDUSTRY

To the Editor:—I would greatly appreciate any information you can give me on eye conditions peculiar to workers in the hair industries, especially in regard to any type of keratitis. Is keratitis punctata superficialis ever due to or influenced by working in hair (animal)? Please omit name.

M.D., Chicago.

ANSWER:—The presence of loose hairs of almost any sort in the conjunctival sac can lead easily to a form of keratitis that may resemble a keratitis punctata superficialis. It is believed that the corneal trouble is of a traumatic nature, as the loose and somewhat stiffened ends of the hairs rub against the corneal epithelium, producing almost microscopic abrasions. These erosions become lightly infiltrated and the clinical picture of a superficial punctate keratitis results. This coincides with the condition that is known to be due to caterpillar hairs in the conjunctival sac. A true keratitis punctata superficialis is believed to be due to an infection (Wright) and not to trauma.

TOXICITY OF PANCREATIN

To the Editor:—The dose of pancreas desiccated or pancreatin as given in the textbooks is from 2 to 5 grains. I would like to know whether it is toxic when given in large quantities and if toxic how it is manifested clinically.

SAMUEL GORSKY, M.D., Philadelphia.

ANSWER:—Pancreatin administered by mouth is not toxic. It can be given in much larger than the official doses; e. g., in quantities of 4 Gm. or more.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written (Group B candidates).* The examination will be held in various cities throughout the country, April 29. *Oral (Group A and Group B candidates).* New York, June 10. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 10. Sec., Dr. William H. Wilder, 122 S. Michigan Blvd., Chicago.

ARIZONA: *Basic Science.* Tucson, Dec. 18. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical.* Phoenix, Jan. 2-3. Sec., Dr. J. H. Patterson, 320 Security Bldg., Phoenix.

CALIFORNIA: *Reciprocity.* Los Angeles, Dec. 5. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Endorsement.* Hartford, Nov. 27. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: Wilmington, Dec. 11-13. Sec., Dr. Harold L. Springer, 1013 Washington St., Wilmington.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, Dec. 27-28. *Medical.* Washington, Jan. 14-15. Sec., Commission on Licensure, Dr. W. C. Fowler, 203 District Bldg., Washington.

KANSAS: Topeka, Dec. 11-12. Sec., Dr. C. H. Ewing, Larned.

KENTUCKY: Louisville, Dec. 4-6. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MARYLAND: *Regular.* Baltimore, Dec. 11-14. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore. *Homeopathic.* Baltimore, Dec. 11-12. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MINNESOTA: *Basic Science.* Minneapolis, Jan. 2-3. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical.* Minneapolis, Jan. 15-17. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* The examinations will be held in medical centers where there are five or more candidates, Feb. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

NEBRASKA: Lincoln, Nov. 22-23. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NORTH CAROLINA: *Endorsement.* Raleigh, Dec. 3. Sec., Dr. Benj. J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, Jan. 1-4. Sec., Dr. G. M. Williamson, 4½ S. 3d St., Grand Forks.

OHIO: Columbus, Dec. 3-6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: *Reciprocity.* Oklahoma City, Dec. 11. Sec., Dr. J. M. Byrum, Mammoth Bldg., Shawnee.

OREGON: Portland, Jan. 2-4. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

TEXAS: Galveston, Nov. 20-22. Sec., Dr. T. J. Crowe, 918 Mercantile Bank Bldg., Dallas.

VIRGINIA: Richmond, Dec. 12-14. Sec., Dr. J. W. Preston, 803 Medical Arts Bldg., Roanoke.

WISCONSIN: *Basic Science.* Milwaukee, Dec. 15. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

National Board of Medical Examiners

The National Board of Medical Examiners reports that its certificate was awarded to 355 candidates who passed the final examination held during June and July, 1934. The following schools were represented:

Wisconsin June Examination

Dr. Robert E. Flynn, secretary, Wisconsin State Board of Medical Examiners, reports the written and practical examination held in Milwaukee, June 26-29, 1934. The examination covered 19 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and five candidates were examined, 101 of whom passed and 4 failed. Twelve applicants were licensed by reciprocity. The following schools were represented:

Book Notices

A Text-Book of Pathology: An Introduction to Medicine. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology in the University of Manitoba. Second edition. Cloth. Price, \$10. Pp. 1047, with 424 illustrations. Philadelphia: Lea & Febiger, 1934.

The appearance of the second edition of a textbook of pathology two years after its first publication is good evidence that it has been received with favor. Much new material has been introduced, notably paragraphs about glycogen storage (von Gierke's disease), on rhinosporidiosis, on medionecrosis of the aorta, on renal architecture in chronic Bright's disease (Oliver's work), on arrhenoblastoma, and on recent observations on encephalitis. In the part on general pathology, certain changes have been made in the order of the chapters so as to secure a more logical sequence. The part on immunity and allergy "has been entirely rewritten" and perhaps this is the part of the book that is in the greatest need of still further revision in the interest of greater clarity, simplification and better emphasis on the essentials as well as avoidance of contradictions. The section on epidemics is superficial and fails to take into consideration that epidemic diseases differ fundamentally in their ways of spreading. To say that "in epidemiology as in metaphysics there is more guesswork than solid ground" is an unhappy and unwise "wise crack." On page 168 one reads of guinea-pigs being injected with horse serum "in an amount even as small as 1 to 1,000 cc.," but otherwise the proofreading seems to have been done with great care. But what can this statement on page 159 mean? "An injection of so minute a dose as 0.1 cc. of immune serum will protect a monkey against yellow fever, and the same is true of measles and dog distemper." The second part, on special pathology, seems to answer the purpose of introducing the student to the study of medicine exceptionally well. In future editions, the efforts to avoid unnecessary repetitions in the second part of statements in the first part and vice versa should be continued. A new chapter dealing with some of the principal diseases of the teeth has been added.

Die Haut- und Geschlechtskrankheiten: Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 15, Band V. Die Behandlung des Trippers beim Manne. Von Prof. Dr. Georg Birnbaum. Instrumentelle Behandlung des Trippers beim Manne. Von Dr. Alois Glingar. Die Heilung des Trippers und deren Feststellung beim Manne. Von Prof. Dr. Karl Zieler. Der Tripper des Weibes. Von Prof. Dr. Konstantin J. Bucura. Paper. Price, 8 marks. Pp. 177-346, with 51 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

This number is divided into four parts, each contributed by an authority on his subject. Professor Birnbaum's article on the treatment of gonorrhea in the male is inclusive and expresses the most modern concept of conservative therapy. Dr. Glingar contributes a thoroughly complete exposition of the instrumental treatment of gonorrheal infection in the male. The article by Dr. Zieler on the cure and determination of cure in the male is excellent. He elaborates on the methods of determining whether a patient has been cured and states that results are from 98 to 99 per cent accurate by modern provocative tests and careful and repeated subsequent examinations. A masterly discussion of gonorrheal infection in the female is the contribution of Professor Bucura of Vienna. This article is brilliantly illustrated with excellent anatomic drawings and histologic preparations.

Your Meals and Your Money. By Gove Hambridge. Cloth. Price, \$1.50. Pp. 190, with illustrations. New York & London: Whittelsey House, McGraw-Hill Book Company, Inc., 1934.

Gove Hambridge turns from the stimulating philosophy of his previous book, *Time to Live*, to the hard facts in a way that demands attention. He warns scientific readers that his presentation will sometimes make the scientist's hair stand on end, but he makes no apology for so doing because he wants people to read the book—and it would seem that they certainly ought to. The book is an effort to translate adequate diet into dollars and cents. The author divides families into four groups: those who earn \$3,000 a year or more, those who earn from \$1,800 to \$3,000, those who earn from \$1,000 to \$1,800 and those who

earn less than \$1,000. For each income group he has a plan according to which the housewife may know exactly how much she should spend for food to make sure that the diet contains adequate amounts of essential food material and that money is not wasted on dietary nonessentials. The book is full of tables, graphs and charts. It would repay careful study on the part of every mother who is faced with the serious problem of feeding the family on a limited budget; for the woman who does not need to count her pennies, it would be just as beneficial in teaching her to get the most food for her food dollar. It should help many a physician to answer the questions of his patients who, when he has prescribed a diet, counter with the despairing query "But doctor how can I afford it?"

Clinical, Pathogenetic and Experimental Investigations of Endometriosis, Especially Regarding the Localisation in the Abdominal Wall (Laparotomy Scars) with a Contribution to the Study of Experimental Transplantation of Endometrium. By Hans Fredrick Harbitz. *Aeta chirurgica Scandinavica*, Vol. LXXIV. Supplementum XXX. Paper. Pp. 400, with 70 illustrations. Oslo: Kristes Boktrykkeri, 1934.

The author, who is the son of Prof. Francis Harbitz, director of the Institute of Pathology in Oslo, derived his incentive for the preparation of this monograph chiefly from his interest in the subject of extraperitoneal endometriosis in the abdominal wall, especially in laparotomy scars. The work consists of three sections. The first deals with endometriosis in general, including a review of all the theories of its pathogenesis, the author himself favoring the well known retrograde implantation theory of Sampson.

The second section is probably the most valuable of the three, comprising, as it does, a meticulous study of 193 cases of endometriosis in abdominal scars gathered from the literature, including the author's own fifteen cases. This portion is a storehouse of information for any one interested in this special subject. Here again the author believes that implantation or direct ingrowth is the responsible factor, although in some instances his efforts to apply this concept may seem quite labored. The third division of the work details the author's own experimental studies on the transplantation of endometrium in rabbits, including transplantation into the abdominal wall and in laparotomy wounds. A short summary of the monograph in English, German and French concludes the volume. An excellent bibliography is included, while the illustrations, chiefly reproductions of photomicrographs, are quite good. The translation of Harbitz's work was, according to the author's preface, done chiefly by H. Yourelle, director of the Berlitz School in Oslo, and this may explain an occasional quaintness of term or expression, e. g., "endometriotic," "Sampson complexes." The monograph should be of interest and value to every one interested in endometriosis, and particularly to those who might be seeking a collective review of the subject of endometriosis in laparotomy scars.

Practical Talks on Heart Disease. By George L. Carlisle, M.D., Associate Professor of Clinical Medicine, Baylor University, Dallas, Texas. Cloth. Price, \$2. Pp. 153. Springfield & Baltimore: Charles C. Thomas, 1934.

There can be no doubt that there is a real need for a book presenting in simple fashion the practical aspects of heart disease. Such simplicity is fraught with the risk of presenting the subject dogmatically and at times inaccurately. This is the most serious defect in the present volume. This book is not so well suited for the general practitioner getting his first knowledge of the modern aspects of heart disease as for the well versed general practitioner, the internist and even the "embryo" cardiologist. The book presupposes a working knowledge of heart disease. One cannot learn about heart disease solely from reading the book. Its chief asset is the attempt of the author to point out a few of the more important errors commonly made in considering diseases of the heart. This is done in vivid and homely language. The text would have been greatly improved had greater care been given to its style, and none of its forcefulness would have been lost if the language had been somewhat more polished. A style suitable for oral argument is not always appropriate for a manuscript. The vigorous advocacy by the author of the use of special antiserum and vaccine in handling rheumatic fever is unwarranted and unjustified at present in view of the experience of experts in this field. Its dogmatism will not bear critical examination.

Thérapeutique hydro-climatique des maladies non tuberculeuses de l'appareil respiratoire. Par M. Pléry, professeur d'hydrologie thérapeutique et de climatologie à la Faculté de médecine de Lyon. Paper. Price, 20 francs. Pp. 159, with 20 illustrations. Paris: Masson & Cie, 1934.

This is devoted to a discussion of nontuberculous diseases of the respiratory tract. A historical sketch of the treatment by hydrotherapy and climate begins with ancient times and carries through each period to the present. One chapter is devoted to the general action of mineral waters and various climates, which includes a map to show where in France various mineral waters are to be found. Another chapter is devoted to the indications of hydrotherapy and climatic conditions in nontuberculous diseases of the respiratory tract. In this chapter are discussed chronic bronchitis, pulmonary emphysema, asthma and chronic pulmonary suppurations. Roentgenograms of the chest and photographs of patients before and after treatment are reproduced. One chapter, which is profusely illustrated, is devoted to the technic and control of the treatment. The author is quite enthusiastic over the results of the treatment.

Sunshine Preferred: The Philosophy of an Ordinary Woman. By Anne Ellis. Cloth. Price, \$2. Pp. 249. Boston & New York: Houghton Mifflin Company, 1934.

This is a highly emotional introspection on the part of a woman evidently afflicted with asthma, who for some unexplainable reason seeks relief in a succession of tuberculosis sanatoriums. She seems to have a perverse urge to do the things that she ought not to do and constantly to court disaster by undertaking what she is physically unable to accomplish. She has a low opinion of doctors; but this is not surprising, since she would not take medical advice except so far as it seemed to please her. The doctor she seems to like best is one who prescribes for her when she is in the Southwest and he is on the Eastern seaboard. It does not appear that he ever examined her. The book would probably make valuable reading for doctors, who might find in it some explanation of why patients sometimes act the way they do. It certainly is not to be recommended for reading by patients, particularly the tuberculous. The book may be good literature but it is certainly not good hygiene.

Keeping Young in Business. By E. B. Weiss and Louis L. Snyder. Cloth. Price, \$1.75. Pp. 182. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc., 1931.

Under this intriguing title the authors have set forth in an interesting manner well known principles of physical and mental hygiene. There is nothing particularly new in the book, but the material is fundamentally sound and is well presented. The twenty-five health commandments will warrant careful attention. The business man who has allowed his job to boss him instead of being the boss of his job would do well to read and to heed. An interesting chapter is the one on "Making a Job for Yourself" and pointing out how individuals who have been thrown out of work during the depression have in some instances been able to make new jobs for themselves and thus have rescued themselves not only from economic shipwreck but also from mental and physical deterioration.

Die klinische Röntgendiagnostik der inneren Erkrankungen. Von Dr. Herbert Assmann, o. Professor und Direktor der medizinischen Klinik an der Universität Königsberg i. Pr. Fifth edition. Teile I und 2. Paper. Price, 87 marks. Pp. 1248, with 1226 illustrations. Berlin: F. C. W. Vogel, 1934.

A scientific work that goes through five editions in thirteen years does not need any further praise of its merits. A majority of the roentgenologists in this country are familiar with this standard book, probably because the exhaustive presentation of the subject is supplemented by a profusion of excellent roentgenograms, photographs of anatomic specimens, charts and diagrams, thus offering a combination of a reference book and an atlas. The first volume is devoted to a roentgenographic diagnosis of the circulatory organs, mediastinum and respiratory system, including the mediastinum, while the second volume is dealing with the diagnosis of diseases of the gastro-intestinal tract, various abdominal organs such as the liver, spleen and pancreas, the urinary system, the nervous system, the bones, the muscles, the tendons and the subcutaneous tissue. Recent methods of angiography, pyclography, hepatolienography and

ventriculography have received due consideration. The author deserves credit for a judicious evaluation of these methods and lack of unwarranted, premature overenthusiasm. Unfortunately, the bibliography entirely disregards foreign literature. In the chapter on examination of the duodenum the author expresses a mythical belief that, contrary to the Viennese school, which advocates fluoroscopic examinations, the American method employs radiography exclusively. Every well trained American roentgenologist is well aware of the fact that fluoroscopy and radiography supplement each other and that, in order to arrive at a correct diagnosis, both methods must be employed. No further adverse criticism can be offered, as the presentation of the subject is complete and clear, the style fluent and the roentgenograms reproduced exceedingly well.

Green's Manual of Pathology. Revised by H. W. C. Vines, M.A., M.D., Pathologist to Charing Cross Hospital, London. American edition edited by Kenneth M. Lynch, M.D., LL.D., Professor of Pathology, Medical College of the State of South Carolina. Fifteenth edition. Cloth. Price, \$6.50. Pp. 928, with 425 illustrations. Baltimore: William Wood & Company, 1934.

The first edition of this book was published in 1876. It has been revised and enlarged many times by different editors. From the beginning, so-called American editions have been issued apparently without any other change than in the names of the publishers. Even in the present edition English spelling and nomenclature prevail, which may be of disadvantage to the American student especially in the case of nomenclature. Many of the illustrations do not illustrate and should have been omitted. The text is fairly good in many parts but decidedly poor in spots. There is no escape from the judgment that the many revisions and expansions have resulted in a patchwork and that the book cannot be recommended as desirable for the use of American medical students at this time.

Untersuchungsmethoden für Arzneispezialitäten. Zusammengestellt von der Spezialitäten-Kommission des Internationalen Apothekerbundes: Prof. Dr. H. Thoms, Berlin, Dr. A. Risling, Stockholm, Prof. Dr. H. Baggesgaard Rasmussen, Kopenhagen, Prof. Dr. H. Hérissé, Paris, Prof. Dr. L. Van Halbe, Leyde, und Hofrat Dr. E. Wels, Wien. Unter Mitarbeit von Dr. E. Høst Madsen, Kopenhagen, und Priv. Doz. Dr. E. Schulek, Budapest. Boards. Price, 5 marks; 3 florins. Pp. 87, with 7 illustrations. Leiden: Fédération Internationale Pharmaceutique; Amsterdam: D. B. Centen's Wetenschappelijke Boekhandel, 1932.

This book describes a series of chemical methods that the Specialty Commission of the International Apothecary Association has chosen as a guide for use in the examination of medicinal products in general, and especially specialty products. Most of the methods are standard and are to be found in pharmaceutical chemistry textbooks but not in as compact form as they are given here. The volume may be considered in two main divisions, the first containing general methods and the second a short outline on the examination of tablets. In addition, there are three short chapters on quantitative alkaloid determinations, one of which bears the name of E. Schulek of Budapest, who was a guest in the A. M. A. Chemical Laboratory several years ago. It must not be considered that such a book can be mastered and that with knowledge so gained one can successfully analyze medicinal products. This type of chemical investigation is possible only if the investigator has the ability to develop new methods and devise applications of older methods to his problems. Ability of this type is the result of experience and cannot come from an outline guide or a book of methods.

The Radiology of Bones and Joints. By James F. Brallsford, M.D., M.R.C.S., Radiological Demonstrator in Living Anatomy, the University of Birmingham. Cloth. Price, \$9. Pp. 500, with 310 illustrations. Baltimore: William Wood & Company, 1934.

The author is well known for his many excellent articles, especially on roentgenology of the spine. He credits Mr. Naughton Dunn, one of England's leading orthopedic surgeons, with considerable help in supplying the material for his book. Almost all bone lesions are described and well illustrated by roentgenograms and line drawings. Unusual bone lesions are briefly described and illustrated. The author stresses periodic examination of lesions that cannot be diagnosed on the first roentgen examination. The book is up to date, easily read, and should be of value to all radiologists and bone and joint surgeons.

Medicolegal

Evidence: Qualifications of Expert Witnesses.—The plaintiff was the beneficiary of an accident insurance policy issued to her husband by the defendant company. The insured was found dead in his garage. In an action to recover on the policy, the trial court permitted the coroner, who was not a physician but an undertaker, to testify that the insured died from carbon monoxide poisoning, a cause of death not covered by the policy. From a judgment for the defendant company, the plaintiff appealed to the Supreme Court of Minnesota, after having been denied a new trial.

On appeal, the plaintiff contended, among other things, that the trial court erred in permitting the coroner to testify as to the cause of death. What caused the death of the insured, said the Supreme Court, was for the jury to determine. If the jury could be aided in determining that issue by the testimony and opinion of experts, such testimony was admissible. A physician is generally conceded to be a qualified expert witness as to the cause of death, even though without experience. The criteria of competence of expert witnesses is stated in Jones on Evidence, section 1314, as follows:
